# Appendix D. SQL Conformance

This section attempts to outline to what extent LightDB conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2016. The 2016 version is referred to as ISO/IEC 9075:2016, or simply as SQL:2016. The versions prior to that were SQL:2011, SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. LightDB development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)
- ISO/IEC 9075-15 Multi-dimensional arrays (SQL/MDA)

The LightDB core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4, 10, and 15 for LightDB.

LightDB supports most of the major features of SQL:2016. Out of 177 mandatory features required for full Core conformance, LightDB conforms to at least 170. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2016.

In the following two sections, we provide a list of those features that LightDB supports, followed by a list of the features defined in SQL:2016 which are not yet supported in LightDB. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

### Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

## D.1. Supported Features

Identifier	Core?	Description	Comment
B012		Embedded C	
B021		Direct SQL	
E011	Core	Numeric data types	
E011-01	Core	INTEGER and SMALLINT data types	
E011-02	Core	REAL, DOUBLE PRECISION, and FLOAT data types	
E011-03	Core	DECIMAL and NUMERIC data types	
E011-04	Core	Arithmetic operators	
E011-05	Core	Numeric comparison	
E011-06	Core	Implicit casting among the numeric data types	
E021	Core	Character data types	
E021-01	Core	CHARACTER data type	
E021-02	Core	CHARACTER VARYING data type	
E021-03	Core	Character literals	
E021-04	Core	CHARACTER_LENGTH function	trims trailing spaces from CHARACTER values before counting
E021-05	Core	OCTET_LENGTH function	
E021-06	Core	SUBSTRING function	
E021-07	Core	Character concatenation	
E021-08	Core	UPPER and LOWER functions	
E021-09	Core	TRIM function	
E021-10	Core	Implicit casting among the character string types	
E021-11	Core	POSITION function	
E021-12	Core	Character comparison	
E031	Core	Identifiers	
E031-01	Core	Delimited identifiers	

Identifier	Core?	Description	Comment
E031-02	Core	Lower case identifiers	
E031-03	Core	Trailing underscore	
E051	Core	Basic query specification	
E051-01	Core	SELECT DISTINCT	
E051-02	Core	GROUP BY clause	
E051-04	Core	GROUP BY can contain columns not in <select list>	
E051-05	Core	Select list items can be renamed	
E051-06	Core	HAVING clause	
E051-07	Core	Qualified * in select list	
E051-08	Core	Correlation names in the FROM clause	
E051-09	Core	Rename columns in the FROM clause	
E061	Core	Basic predicates and search conditions	
E061-01	Core	Comparison predicate	
E061-02	Core	BETWEEN predicate	
E061-03	Core	IN predicate with list of values	
E061-04	Core	LIKE predicate	
E061-05	Core	LIKE predicate ESCAPE clause	
E061-06	Core	NULL predicate	
E061-07	Core	Quantified comparison predicate	
E061-08	Core	EXISTS predicate	
E061-09	Core	Subqueries in comparison predicate	
E061-11	Core	Subqueries in IN predicate	
E061-12	Core	Subqueries in quantified comparison predicate	
E061-13	Core	Correlated subqueries	
E061-14	Core	Search condition	
E071	Core	Basic query expressions	
E071-01	Core	UNION DISTINCT table operator	
E071-02	Core	UNION ALL table operator	
E071-03	Core	EXCEPT DISTINCT table operator	
E071-05	Core	Columns combined via table operators need not have exactly the same data type	
E071-06	Core	Table operators in subqueries	
E081	Core	Basic Privileges	
E081-01	Core	SELECT privilege	
E081-02	Core	DELETE privilege	
E081-03	Core	INSERT privilege at the table level	
E081-04	Core	UPDATE privilege at the table level	
E081-05	Core	UPDATE privilege at the column level	
E081-06	Core	REFERENCES privilege at the table level	
E081-07	Core	REFERENCES privilege at the column level	
E081-08	Core	WITH GRANT OPTION	

<b>Identifier</b>	<b>Core?</b>	<b>Description</b>	<b>Comment</b>
E081-09	Core	USAGE privilege	
E081-10	Core	EXECUTE privilege	
E091	Core	Set functions	
E091-01	Core	AVG	
E091-02	Core	COUNT	
E091-03	Core	MAX	
E091-04	Core	MIN	
E091-05	Core	SUM	
E091-06	Core	ALL quantifier	
E091-07	Core	DISTINCT quantifier	
E101	Core	Basic data manipulation	
E101-01	Core	INSERT statement	
E101-03	Core	Searched UPDATE statement	
E101-04	Core	Searched DELETE statement	
E111	Core	Single row SELECT statement	
E121	Core	Basic cursor support	
E121-01	Core	DECLARE CURSOR	
E121-02	Core	ORDER BY columns need not be in select list	
E121-03	Core	Value expressions in ORDER BY clause	
E121-04	Core	OPEN statement	
E121-06	Core	Positioned UPDATE statement	
E121-07	Core	Positioned DELETE statement	
E121-08	Core	CLOSE statement	
E121-10	Core	FETCH statement implicit NEXT	
E121-17	Core	WITH HOLD cursors	
E131	Core	Null value support (nulls in lieu of values)	
E141	Core	Basic integrity constraints	
E141-01	Core	NOT NULL constraints	
E141-02	Core	UNIQUE constraints of NOT NULL columns	
E141-03	Core	PRIMARY KEY constraints	
E141-04	Core	Basic FOREIGN KEY constraint with the NO ACTION default for both referential delete action and referential update action	
E141-06	Core	CHECK constraints	
E141-07	Core	Column defaults	
E141-08	Core	NOT NULL inferred on PRIMARY KEY	
E141-10	Core	Names in a foreign key can be specified in any order	
E151	Core	Transaction support	
E151-01	Core	COMMIT statement	
E151-02	Core	ROLLBACK statement	
E152	Core	Basic SET TRANSACTION statement	

Identifier	Core?	Description	Comment
E152-01	Core	SET TRANSACTION statement: ISOLATION LEVEL SERIALIZABLE clause	
E152-02	Core	SET TRANSACTION statement: READ ONLY and READ WRITE clauses	
E153	Core	Updatable queries with subqueries	
E161	Core	SQL comments using leading double minus	
E171	Core	SQLSTATE support	
E182	Core	Host language binding	
F021	Core	Basic information schema	
F021-01	Core	COLUMNS view	
F021-02	Core	TABLES view	
F021-03	Core	VIEWS view	
F021-04	Core	TABLE_CONSTRAINTS view	
F021-05	Core	REFERENTIAL_CONSTRAINTS view	
F021-06	Core	CHECK_CONSTRAINTS view	
F031	Core	Basic schema manipulation	
F031-01	Core	CREATE TABLE statement to create persistent base tables	
F031-02	Core	CREATE VIEW statement	
F031-03	Core	GRANT statement	
F031-04	Core	ALTER TABLE statement: ADD COLUMN clause	
F031-13	Core	DROP TABLE statement: RESTRICT clause	
F031-16	Core	DROP VIEW statement: RESTRICT clause	
F031-19	Core	REVOKE statement: RESTRICT clause	
F032		CASCADE drop behavior	
F033		ALTER TABLE statement: DROP COLUMN clause	
F034		Extended REVOKE statement	
F034-01		REVOKE statement performed by other than the owner of a schema object	
F034-02		REVOKE statement: GRANT OPTION FOR clause	
F034-03		REVOKE statement to revoke a privilege that the grantee has WITH GRANT OPTION	
F041	Core	Basic joined table	
F041-01	Core	Inner join (but not necessarily the INNER keyword)	
F041-02	Core	INNER keyword	
F041-03	Core	LEFT OUTER JOIN	
F041-04	Core	RIGHT OUTER JOIN	
F041-05	Core	Outer joins can be nested	
F041-07	Core	The inner table in a left or right outer join can also be used in an inner join	
F041-08	Core	All comparison operators are supported (rather than just =)	
F051	Core	Basic date and time	

Identifier	Core?	Description	Comment
F051-01	Core	DATE data type (including support of DATE literal)	
F051-02	Core	TIME data type (including support of TIME literal) with fractional seconds precision of at least 0	
F051-03	Core	TIMESTAMP data type (including support of TIMESTAMP literal) with fractional seconds precision of at least 0 and 6	
F051-04	Core	Comparison predicate on DATE, TIME, and TIMESTAMP data types	
F051-05	Core	Explicit CAST between datetime types and character string types	
F051-06	Core	CURRENT_DATE	
F051-07	Core	LOCALTIME	
F051-08	Core	LOCALTIMESTAMP	
F052		Intervals and datetime arithmetic	
F053		OVERLAPS predicate	
F081	Core	UNION and EXCEPT in views	
F111		Isolation levels other than SERIALIZABLE	
F111-01		READ UNCOMMITTED isolation level	
F111-02		READ COMMITTED isolation level	
F111-03		REPEATABLE READ isolation level	
F131	Core	Grouped operations	
F131-01	Core	WHERE, GROUP BY, and HAVING clauses supported in queries with grouped views	
F131-02	Core	Multiple tables supported in queries with grouped views	
F131-03	Core	Set functions supported in queries with grouped views	
F131-04	Core	Subqueries with GROUP BY and HAVING clauses and grouped views	
F131-05	Core	Single row SELECT with GROUP BY and HAVING clauses and grouped views	
F171		Multiple schemas per user	
F181	Core	Multiple module support	
F191		Referential delete actions	
F200		TRUNCATE TABLE statement	
F201	Core	CAST function	
F202		TRUNCATE TABLE: identity column restart option	
F221	Core	Explicit defaults	
F222		INSERT statement: DEFAULT VALUES clause	
F231		Privilege tables	
F231-01		TABLE_PRIVILEGES view	
F231-02		COLUMN_PRIVILEGES view	
F231-03		USAGE_PRIVILEGES view	
F251		Domain support	

Identifier	Core?	Description	Comment
F261	Core	CASE expression	
F261-01	Core	Simple CASE	
F261-02	Core	Searched CASE	
F261-03	Core	NULLIF	
F261-04	Core	COALESCE	
F262		Extended CASE expression	
F271		Compound character literals	
F281		LIKE enhancements	
F302		INTERSECT table operator	
F302-01		INTERSECT DISTINCT table operator	
F302-02		INTERSECT ALL table operator	
F304		EXCEPT ALL table operator	
F311	Core	Schema definition statement	
F311-01	Core	CREATE SCHEMA	
F311-02	Core	CREATE TABLE for persistent base tables	
F311-03	Core	CREATE VIEW	
F311-04	Core	CREATE VIEW: WITH CHECK OPTION	
F311-05	Core	GRANT statement	
F321		User authorization	
F361		Subprogram support	
F381		Extended schema manipulation	
F381-01		ALTER TABLE statement: ALTER COLUMN clause	
F381-02		ALTER TABLE statement: ADD CONSTRAINT clause	
F381-03		ALTER TABLE statement: DROP CONSTRAINT clause	
F382		Alter column data type	
F383		Set column not null clause	
F384		Drop identity property clause	
F385		Drop column generation expression clause	
F386		Set identity column generation clause	
F391		Long identifiers	
F392		Unicode escapes in identifiers	
F393		Unicode escapes in literals	
F394		Optional normal form specification	
F401		Extended joined table	
F401-01		NATURAL JOIN	
F401-02		FULL OUTER JOIN	
F401-04		CROSS JOIN	
F402		Named column joins for LOBs, arrays, and multisets	
F411		Time zone specification	differences regarding literal interpretation

Identifier	Core?	Description	Comment
F421		National character	
F431		Read-only scrollable cursors	
F431-01		FETCH with explicit NEXT	
F431-02		FETCH FIRST	
F431-03		FETCH LAST	
F431-04		FETCH PRIOR	
F431-05		FETCH ABSOLUTE	
F431-06		FETCH RELATIVE	
F441		Extended set function support	
F442		Mixed column references in set functions	
F471	Core	Scalar subquery values	
F481	Core	Expanded NULL predicate	
F491		Constraint management	
F501	Core	Features and conformance views	
F501-01	Core	SQL_FEATURES view	
F501-02	Core	SQL_SIZING view	
F502		Enhanced documentation tables	
F531		Temporary tables	
F555		Enhanced seconds precision	
F561		Full value expressions	
F571		Truth value tests	
F591		Derived tables	
F611		Indicator data types	
F641		Row and table constructors	
F651		Catalog name qualifiers	
F661		Simple tables	
F672		Retrospective check constraints	
F690		Collation support	but no character set support
F692		Extended collation support	
F701		Referential update actions	
F711		ALTER domain	
F731		INSERT column privileges	
F751		View CHECK enhancements	
F761		Session management	
F762		CURRENT_CATALOG	
F763		CURRENT_SCHEMA	
F771		Connection management	
F781		Self-referencing operations	
F791		Insensitive cursors	
F801		Full set function	

Identifier	Core?	Description	Comment
F850		Top-level <order by clause> in <query expression>	
F851		<order by clause> in subqueries	
F852		Top-level <order by clause> in views	
F855		Nested <order by clause> in <query expression>	
F856		Nested <fetch first clause> in <query expression>	
F857		Top-level <fetch first clause> in <query expression>	
F858		<fetch first clause> in subqueries	
F859		Top-level <fetch first clause> in views	
F860		<fetch first row count> in <fetch first clause>	
F861		Top-level <result offset clause> in <query expression>	
F862		<result offset clause> in subqueries	
F863		Nested <result offset clause> in <query expression>	
F864		Top-level <result offset clause> in views	
F865		<offset row count> in <result offset clause>	
F867		FETCH FIRST clause: WITH TIES option	
S071		SQL paths in function and type name resolution	
S092		Arrays of user-defined types	
S095		Array constructors by query	
S096		Optional array bounds	
S098		ARRAY_AGG	
S111		ONLY in query expressions	
S201		SQL-invoked routines on arrays	
S201-01		Array parameters	
S201-02		Array as result type of functions	
S211		User-defined cast functions	
S301		Enhanced UNNEST	
T031		BOOLEAN data type	
T071		BIGINT data type	
T121		WITH (excluding RECURSIVE) in query expression	
T122		WITH (excluding RECURSIVE) in subquery	
T131		Recursive query	
T132		Recursive query in subquery	
T141		SIMILAR predicate	
T151		DISTINCT predicate	
T152		DISTINCT predicate with negation	
T171		LIKE clause in table definition	
T172		AS subquery clause in table definition	
T173		Extended LIKE clause in table definition	
T174		Identity columns	
T177		Sequence generator support: simple restart option	
T178		Identity columns: simple restart option	

Identifier	Core?	Description	Comment
T191		Referential action RESTRICT	
T201		Comparable data types for referential constraints	
T211-01		Triggers activated on UPDATE, INSERT, or DELETE of one base table	
T211-02		BEFORE triggers	
T211-03		AFTER triggers	
T211-04		FOR EACH ROW triggers	
T211-05		Ability to specify a search condition that must be true before the trigger is invoked	
T211-07		TRIGGER privilege	
T212		Enhanced trigger capability	
T213		INSTEAD OF triggers	
T231		Sensitive cursors	
T241		START TRANSACTION statement	
T261		Chained transactions	
T271		Savepoints	
T281		SELECT privilege with column granularity	
T285		Enhanced derived column names	
T312		OVERLAY function	
T321-01	Core	User-defined functions with no overloading	
T321-02	Core	User-defined stored procedures with no overloading	
T321-03	Core	Function invocation	
T321-04	Core	CALL statement	
T321-06	Core	ROUTINES view	
T321-07	Core	PARAMETERS view	
T323		Explicit security for external routines	
T325		Qualified SQL parameter references	
T331		Basic roles	
T341		Overloading of SQL-invoked functions and procedures	
T351		Bracketed SQL comments (/*...*/ comments)	
T431		Extended grouping capabilities	
T432		Nested and concatenated GROUPING SETS	
T433		Multiargument GROUPING function	
T441		ABS and MOD functions	
T461		Symmetric BETWEEN predicate	
T491		LATERAL derived table	
T501		Enhanced EXISTS predicate	
T521		Named arguments in CALL statement	
T523		Default values for INOUT parameters of SQL-invoked procedures	
T524		Named arguments in routine invocations other than a CALL statement	

Identifier	Core?	Description	Comment
T525		Default values for parameters of SQL-invoked functions	
T551		Optional key words for default syntax	
T581		Regular expression substring function	
T591		UNIQUE constraints of possibly null columns	
T611		Elementary OLAP operations	
T612		Advanced OLAP operations	
T613		Sampling	
T614		NTILE function	
T615		LEAD and LAG functions	
T617		FIRST_VALUE and LAST_VALUE function	
T620		WINDOW clause: GROUPS option	
T621		Enhanced numeric functions	
T622		Trigonometric functions	
T623		General logarithm functions	
T624		Common logarithm functions	
T631	Core	IN predicate with one list element	
T651		SQL-schema statements in SQL routines	
T653		SQL-schema statements in external routines	
T655		Cyclically dependent routines	
T831		SQL/JSON path language: strict mode	
T832		SQL/JSON path language: item method	
T833		SQL/JSON path language: multiple subscripts	
T834		SQL/JSON path language: wildcard member accessor	
T835		SQL/JSON path language: filter expressions	
T836		SQL/JSON path language: starts with predicate	
T837		SQL/JSON path language: regex_like predicate	
X010		XML type	
X011		Arrays of XML type	
X014		Attributes of XML type	
X016		Persistent XML values	
X020		XMLConcat	
X031		XMLElement	
X032		XMLForest	
X034		XMLAgg	
X035		XMLAgg: ORDER BY option	
X036		XMLComment	
X037		XMLPI	
X040		Basic table mapping	
X041		Basic table mapping: nulls absent	
X042		Basic table mapping: null as nil	

Identifier	Core?	Description	Comment
X043		Basic table mapping: table as forest	
X044		Basic table mapping: table as element	
X045		Basic table mapping: with target namespace	
X046		Basic table mapping: data mapping	
X047		Basic table mapping: metadata mapping	
X048		Basic table mapping: base64 encoding of binary strings	
X049		Basic table mapping: hex encoding of binary strings	
X050		Advanced table mapping	
X051		Advanced table mapping: nulls absent	
X052		Advanced table mapping: null as nil	
X053		Advanced table mapping: table as forest	
X054		Advanced table mapping: table as element	
X055		Advanced table mapping: with target namespace	
X056		Advanced table mapping: data mapping	
X057		Advanced table mapping: metadata mapping	
X058		Advanced table mapping: base64 encoding of binary strings	
X059		Advanced table mapping: hex encoding of binary strings	
X060		XMLParse: character string input and CONTENT option	
X061		XMLParse: character string input and DOCUMENT option	
X070		XMLSerialize: character string serialization and CONTENT option	
X071		XMLSerialize: character string serialization and DOCUMENT option	
X072		XMLSerialize: character string serialization	
X090		XML document predicate	
X120		XML parameters in SQL routines	
X121		XML parameters in external routines	
X221		XML passing mechanism BY VALUE	
X301		XMLTable: derived column list option	
X302		XMLTable: ordinality column option	
X303		XMLTable: column default option	
X304		XMLTable: passing a context item	must be XML DOCUMENT
X400		Name and identifier mapping	
X410		Alter column data type: XML type	

## D.2. Unsupported Features

The following features defined in SQL:2016 are not implemented in this release of LightDB. In a few cases, equivalent functionality is available.

Identifier	Core?	Description	Comment
B011		Embedded Ada	
B013		Embedded COBOL	
B014		Embedded Fortran	
B015		Embedded MUMPS	
B016		Embedded Pascal	
B017		Embedded PL/I	
B031		Basic dynamic SQL	
B032		Extended dynamic SQL	
B032-01		<describe input statement>	
B033		Untyped SQL-invoked function arguments	
B034		Dynamic specification of cursor attributes	
B035		Non-extended descriptor names	
B041		Extensions to embedded SQL exception declarations	
B051		Enhanced execution rights	
B111		Module language Ada	
B112		Module language C	
B113		Module language COBOL	
B114		Module language Fortran	
B115		Module language MUMPS	
B116		Module language Pascal	
B117		Module language PL/I	
B121		Routine language Ada	
B122		Routine language C	
B123		Routine language COBOL	
B124		Routine language Fortran	
B125		Routine language MUMPS	
B126		Routine language Pascal	
B127		Routine language PL/I	
B128		Routine language SQL	
B200		Polymorphic table functions	
B201		More than one PTF generic table parameter	
B202		PTF Copartitioning	
B203		More than one copartition specification	
B204		PRUNE WHEN EMPTY	
B205		Pass-through columns	
B206		PTF descriptor parameters	
B207		Cross products of partitionings	

Identifier	Core?	Description	Comment
B208		PTF component procedure interface	
B209		PTF extended names	
B211		Module language Ada: VARCHAR and NUMERIC support	
B221		Routine language Ada: VARCHAR and NUMERIC support	
F054		TIMESTAMP in DATE type precedence list	
F121		Basic diagnostics management	
F121-01		GET DIAGNOSTICS statement	
F121-02		SET TRANSACTION statement: DIAGNOSTICS SIZE clause	
F122		Enhanced diagnostics management	
F123		All diagnostics	
F263		Comma-separated predicates in simple CASE expression	
F291		UNIQUE predicate	
F301		CORRESPONDING in query expressions	
F312		MERGE statement	consider INSERT ... ON CONFLICT DO UPDATE
F313		Enhanced MERGE statement	
F314		MERGE statement with DELETE branch	
F341		Usage tables	no ROUTINE_*_USAGE tables
F403		Partitioned joined tables	
F404		Range variable for common column names	
F451		Character set definition	
F461		Named character sets	
F492		Optional table constraint enforcement	
F521		Assertions	
F671		Subqueries in CHECK	intentionally omitted
F673		Reads SQL-data routine invocations in CHECK constraints	
F693		SQL-session and client module collations	
F695		Translation support	
F696		Additional translation documentation	
F721		Deferrable constraints	foreign and unique keys only
F741		Referential MATCH types	no partial match yet
F812	Core	Basic flagging	
F813		Extended flagging	
F821		Local table references	
F831		Full cursor update	

Identifier	Core?	Description	Comment
F831-01		Updatable scrollable cursors	
F831-02		Updatable ordered cursors	
F841		LIKE_REGEX predicate	
F842		OCCURRENCES_REGEX function	
F843		POSITION_REGEX function	
F844		SUBSTRING_REGEX function	
F845		TRANSLATE_REGEX function	
F846		Octet support in regular expression operators	
F847		Nonconstant regular expressions	
F866		FETCH FIRST clause: PERCENT option	
R010		Row pattern recognition: FROM clause	
R020		Row pattern recognition: WINDOW clause	
R030		Row pattern recognition: full aggregate support	
S011	Core	Distinct data types	
S011-01	Core	USER_DEFINED_TYPES view	
S023		Basic structured types	
S024		Enhanced structured types	
S025		Final structured types	
S026		Self-referencing structured types	
S027		Create method by specific method name	
S028		Permutable UDT options list	
S041		Basic reference types	
S043		Enhanced reference types	
S051		Create table of type	partially supported
S081		Subtables	
S091		Basic array support	partially supported
S091-01		Arrays of built-in data types	
S091-02		Arrays of distinct types	
S091-03		Array expressions	
S094		Arrays of reference types	
S097		Array element assignment	
S151		Type predicate	
S161		Subtype treatment	
S162		Subtype treatment for references	
S202		SQL-invoked routines on multisets	
S231		Structured type locators	
S232		Array locators	
S233		Multiset locators	
S241		Transform functions	
S242		Alter transform statement	
S251		User-defined orderings	

Identifier	Core?	Description	Comment
S261		Specific type method	
S271		Basic multiset support	
S272		Multisets of user-defined types	
S274		Multisets of reference types	
S275		Advanced multiset support	
S281		Nested collection types	
S291		Unique constraint on entire row	
S401		Distinct types based on array types	
S402		Distinct types based on distinct types	
S403		ARRAY_MAX_CARDINALITY	
S404		TRIM_ARRAY	
T011		Timestamp in Information Schema	
T021		BINARY and VARBINARY data types	
T022		Advanced support for BINARY and VARBINARY data types	
T023		Compound binary literal	
T024		Spaces in binary literals	
T041		Basic LOB data type support	
T041-01		BLOB data type	
T041-02		CLOB data type	
T041-03		POSITION, LENGTH, LOWER, TRIM, UPPER, and SUBSTRING functions for LOB data types	
T041-04		Concatenation of LOB data types	
T041-05		LOB locator: non-holdable	
T042		Extended LOB data type support	
T043		Multiplier T	
T044		Multiplier P	
T051		Row types	
T053		Explicit aliases for all-fields reference	
T061		UCS support	
T076		DECFLOAT data type	
T101		Enhanced nullability determination	
T111		Updatable joins, unions, and columns	
T175		Generated columns	mostly supported
T176		Sequence generator support	supported except for NEXT VALUE FOR
T180		System-versioned tables	
T181		Application-time period tables	
T211		Basic trigger capability	
T211-06		Support for run-time rules for the interaction of triggers and constraints	

Identifier	Core?	Description	Comment
T211-08		Multiple triggers for the same event are executed in the order in which they were created in the catalog	intentionally omitted
T251		SET TRANSACTION statement: LOCAL option	
T272		Enhanced savepoint management	
T301		Functional dependencies	partially supported
T321	Core	Basic SQL-invoked routines	
T321-05	Core	RETURN statement	
T322		Declared data type attributes	
T324		Explicit security for SQL routines	
T326		Table functions	
T332		Extended roles	mostly supported
T434		GROUP BY DISTINCT	
T471		Result sets return value	
T472		DESCRIBE CURSOR	
T495		Combined data change and retrieval	different syntax
T502		Period predicates	
T511		Transaction counts	
T522		Default values for IN parameters of SQL-invoked procedures	supported except DEFAULT key word in invocation
T561		Holdable locators	
T571		Array-returning external SQL-invoked functions	
T572		Multiset-returning external SQL-invoked functions	
T601		Local cursor references	
T616		Null treatment option for LEAD and LAG functions	
T618		NTH_VALUE function	function exists, but some options missing
T619		Nested window functions	
T625		LISTAGG	
T641		Multiple column assignment	only some syntax variants supported
T652		SQL-dynamic statements in SQL routines	
T654		SQL-dynamic statements in external routines	
T811		Basic SQL/JSON constructor functions	
T812		SQL/JSON: JSON_OBJECTAGG	
T813		SQL/JSON: JSON_ARRAYAGG with ORDER BY	
T814		Colon in JSON_OBJECT or JSON_OBJECTAGG	
T821		Basic SQL/JSON query operators	
T822		SQL/JSON: IS JSON WITH UNIQUE KEYS predicate	
T823		SQL/JSON: PASSING clause	
T824		JSON_TABLE: specific PLAN clause	

Identifier	Core?	Description	Comment

X305		XMLTable: initializing an XQuery variable	

## D.3. XML Limits and Conformance to SQL/XML

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. LightDB's implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold “document” or “content” in untyped or XML Schema-typed variants, and a type XML ( SEQUENCE ) to hold arbitrary pieces of XML content, LightDB provides the single xml type, which can hold “document” or “content”. There is no equivalent of the standard's “sequence” type.
- LightDB provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.

This section presents some of the resulting differences you may encounter.

### D.3.1. Queries Are Restricted to XPath 1.0

The LightDB-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. LightDB also provides XPath-only variants of the standard functions `XMLEXISTS` and `XMLTABLE`, which officially use the XQuery language. For all of these functions, LightDB relies on the libxml2 library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone).

But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the LightDB-specific functions.

### D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

- XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.
- XQuery has control constructs for iteration, sorting, and grouping.
- XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

### D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

- The fundamental type of an XQuery/XPath expression, the `sequence`, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.
- Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.

#### Note

The libxml2 library does seem to always return node-sets to LightDB with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types `boolean`, `double`, and `string`.
- XPath 1.0 has no conditional operator. An XQuery/XPath expression such as `if ( hat ) then hat/@size else "no hat"` has no XPath 1.0 equivalent.
- XPath 1.0 has no ordering comparison operator for strings. Both `"cat" < "dog"` and `"cat" > "dog"` are false, because each is a numeric comparison of two NaNs. In contrast, `=` and `!=` do compare the strings as strings.
- XPath 1.0 blurs the distinction between *value comparisons* and *general comparisons* as XQuery/XPath define them. Both `sale/@hatsize = 7` and `sale/@customer = "alice"` are existentially quantified comparisons, true if there is any `sale` with the given value for the attribute,

but `sale/@taxable = false()` is a value comparison to the *effective boolean value* of a whole node-set. It is true only if no `sale` has a `taxable` attribute at all.

- In the XQuery/XPath data model, a *document node* can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the *root node*, can only be in document form. This is part of the reason an `xml` value passed as the context item to any LightDB XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of function library changes<sup>1</sup> and language changes<sup>2</sup> applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

### D.3.1.3. Mappings between SQL and XML Data Types and Values

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When LightDB maps SQL data values to XML (as in `xmlelement`), or XML to SQL (as in the output columns of `xmltable`), except for a few cases treated specially, LightDB simply assumes that the XML data type's XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard.

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in Section 9.8) explicitly to produce the standard mappings.

## D.3.2. Incidental Limits of the Implementation

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in LightDB.

### D.3.2.1. Only BY VALUE Passing Mechanism Is Supported

The SQL standard defines two *passing mechanisms* that apply when passing an XML argument from SQL to an XML function or receiving a result: `BY REF`, in which a particular XML value retains its node identity, and `BY VALUE`, in which the content of the XML is passed but node identity is not preserved. A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

To illustrate the difference, if `x` is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

```
SELECT XMLQUERY('$a is $b' PASSING BY REF x AS a, x AS b NULL ON
EMPTY);
SELECT XMLQUERY('$a is $b' PASSING BY VALUE x AS a, x AS b NULL ON
EMPTY);
```

LightDB will accept `BY VALUE` or `BY REF` in an `XMLEXISTS` or `XMLTABLE` construct, but it ignores them. The `xml` data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively `BY VALUE`.

<sup>1</sup> <https://www.w3.org/TR/2010/REC-xpath-functions-20101214/#xpath1-compatibility>

<sup>2</sup> <https://www.w3.org/TR/xpath20/#id-backwards-compatibility>

### **D.3.2.2. Cannot Pass Named Parameters to Queries**

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

### **D.3.2.3. No XML ( SEQUENCE ) Type**

The LightDB `xml` data type can only hold a value in `DOCUMENT` or `CONTENT` form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing `CONTENT`. The upshot is that a well-formed `DOCUMENT` is the only form of XML value that LightDB can supply as an XPath context item.

---

# Appendix E. Release Notes

The release notes contain significant changes in each LightDB release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or internal changes which mean not user-visible. For example, the optimizer may be improved in almost every release, but the improvements are usually observed by users as simply faster queries.

## E.1. Release 13.8-23.4

**Release date:** 2023-12-31

### E.1.1. Oracle Compatibility

- Supports the `set definecommand`, which can be used to enable or disable variable replacement functionality. see `set define on/off` command.
- Client command line support `'/`. see `Slashes`.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
  oracle;
\c test_oracle
```

```
Select 1+2;
?column?
-----
3
(1 row)
```

```
/
```

- Uppercase field names can be added with double quotation marks during queries. see `Lexical Structure`.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
  oracle;
\c test_oracle
```

```
create table t1(id int, "Id" int);

insert into t1 values(1,2),(3,4),(5,6);

select "ID" from t1;
  ID
----
  1
  3
  5
(3 rows)
```

- Addition and subtraction of `timestamp,oracle.date` and numeric values are supported. see `orafce`.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

Create table t_data(dt date, d1 integer, d2 bigint, d3 smallint,
d4 numeric(10, 2), dd date);

insert into t_data values(to_date('2023-11-28 20:10:30', 'YYYY-
MM-DD HH24:mi:ss'), 1, 2, 3, 4.4, to_date('2023-11-27 20:10:30',
'YYYY-MM-DD HH24:mi:ss'));

insert into t_data values(to_date('2023-11-28 00:00:01', 'YYYY-
MM-DD HH24:mi:ss'), 1, 2, 3, 4.5, to_date('2023-11-27 00:00:02',
'YYYY-MM-DD HH24:mi:ss'));

select dt, dt - d1, dt - d1 + d2 , dt - d1 + d2 - d3, dt - d1 +
d2 - d3 + d4, dt - dd from t_data;
      dt          |          ?column?          |          ?column?
|          ?column?          |          ?column?          |          ?column?
-----+-----+-----
+-----+-----+-----
+-----+-----+-----
2023-11-28 20:10:30 | 2023-11-27 20:10:30 | 2023-11-29
20:10:30 | 2023-11-26 20:10:30 | 2023-12-01 05:46:30 |
1.00000000000000000000
2023-11-28 00:00:01 | 2023-11-27 00:00:01 | 2023-11-29
00:00:01 | 2023-11-26 00:00:01 | 2023-11-30 12:00:01 |
0.99998842592592592500
(2 rows)
```

- Rownum can be used as an rvalue expression. See ROWNUM.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

SELECT TO_CHAR(TO_DATE(TRIM('20230110'), 'YYYYMMDD') + ROWNUM,
'YYYYMMDD') from dual;
to_char
-----
20230111
(1 row)
```

- The value type in the decode function parameter is equivalent to the invalid 0 in the decimal place of the value. see DECODE.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
```

```

\c test_oracle

SELECT decode(0.0, 0, 1, 2), decode(0, 0, 1, 2), decode(0, 0.0,
  1, 2), decode(0, 1, 2, 0.0, 4, 5) FROM dual;
  decode | decode | decode | decode
-----+-----+-----+-----
         1 |         1 |         1 | 4
(1 row)

```

```

SELECT decode(1.10, 1.1, 1, 2) FROM dual;
  decode
-----
         1
(1 row)

```

```

SELECT decode(1.0, 1, 1, 2) FROM dual;
  decode
-----
         1
(1 row)

```

- The `substr` function supports a combination of `text,numeric,numeric` or `text,numeric`. see `orafce`.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
  oracle;
\c test_oracle

create table tt_substr(a number(10), b number(10));

INSERT INTO tt_substr (a, b) VALUES(2, 1);

select substr('aaaaa'::varchar2, 2, a + b) FROM tt_substr;
  substr
-----
     aaa
(1 row)

select substr('aaaaa'::varchar2, a) FROM tt_substr;
  substr
-----
     aaaa
(1 row)

```

- The `to_char` function changes the date and number format to text format. see `orafce`.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
  oracle;
\c test_oracle

Select to_char(sysdate+1 + interval '-1'
  year,'d','NLS_DATE_LANGUAGE=''SIMPLIFIED CHINESE''');

```

```

to_char
-----
6
(1 row)

```

- The rawtohex function supports the uuid type as a parameter. see orafce.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

select rawtohex(sys_guid()) from dual;
           rawtohex
-----
6653ab0b8ad34634bdc1645f3f264455
(1 row)

```

- The rowidtochar function converts the rowid type to a character type. see orafce.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

create table tt1(idd int);

insert into tt1 values(3);

create table tt7 as select rowidtochar(rowid) as rowid1,* from
tt1;

\d tt7
           Table "public.tt7"
  Column |   Type   | Collation | Nullable | Default
-----+-----+-----+-----+-----
 rowid1 | varchar2 |           |          |
  idd   | integer  |           |          |

```

- The to\_timestamp converts the character time value to a timestamp format. see orafce.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

SELECT TO_TIMESTAMP('2023-10-11 10:10:10', 'YYYY-MM-DD HH:MI:SS
PM') FROM dual;
           to_timestamp
-----
2023-10-11 10:10:10+08
(1 row)

```

- Support `empty_clob/empty_blob` initialization of LOB objects, The return is not null, `empty_blob()` is null is not established. see orafce.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
Select empty_clob();
empty_clob
```

```
-----
```

```
(1 row)
```

```
Select empty_blob();
empty_blob
```

```
-----
```

```
\x
```

```
(1 row)
```

- The `sysimestamp(n)` supports precision parameters. see Date/Time Functions.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
select current_timestamp,sysimestamp(0);
```

```
current_timestamp | sysimestamp
```

```
-----+-----
```

```
2024-01-02 01:48:16.899369-05 | 2024-01-02 01:48:17-05
```

```
(1 row)
```

```
select current_timestamp,sysimestamp(1);
```

```
current_timestamp | sysimestamp
```

```
-----+-----
```

```
2024-01-02 01:48:16.900603-05 | 2024-01-02 01:48:16.9-05
```

- The parameters of the `NVL` function can be set to null. see orafce.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
select nvl(null::numeric, '0');
```

```
nvl
```

```
-----
```

```
0
```

```
(1 row)
```

- The time string of the supported `to_date` function does not match the output data format. see orafce.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

select to_date('2022/02/02','yyyy-mm-dd') from dual;
      to_date
-----
2022-02-02 00:00:00
(1 row)
```

- The `xmlparse` and `xmlagg` functions are supported. see XML Functions.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

SELECT XMLPARSE(CONTENT '124 <purchaseOrder poNo="12435">
<customerName> Acme Enterprises</customerName>
<itemNo>32987457</itemNo>
</purchaseOrder>'
WELLFORMED) AS PO FROM DUAL;

po
-----
124 <purchaseOrder poNo="12435">
<customerName> Acme Enterprises</customerName>
<itemNo>32987457</itemNo>
</purchaseOrder>
(1 row)
```

- Create a partition table name that does not exceed 31 characters in length. see CREATE TABLE.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

CREATE TABLE test_partition_table_len_31__lh(a int,b int)
PARTITION BY list(a)
SUBPARTITION BY hash(b)
(
  PARTITION p11 VALUES(1,2,3,4),
  PARTITION p12 VALUES(5,6,7,8)
);
```

- The object type can be rebuilt by `replace`. see CREATE TYPE.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
CREATE OR REPLACE TYPE employee_type AS OBJECT(
x int,
y int,
MEMBER FUNCTION psum(a int, b int) RETURN int,
MEMBER PROCEDURE p(prompt varchar)
);
CREATE TYPE.
```

- Support commands of alter session enable/disable parallel dml. see ALTER SESSION.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

alter session enable parallel dml;
```

- Supports tabs view, a built-in view of all tablespaces and their associated objects in the database. see orafce.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
CREATE TABLE measurement (
```

```
    city_id          int not null,
    logdate           date not null,
    peaktemp         int,
    unitsales        int
```

```
) PARTITION BY RANGE (logdate);
```

```
SELECT table_name, tablespace_name FROM oracle.TABS WHERE
TABLE_NAME IN ('TEST_VIEW', 'MEASUREMENT', 'MEASUREMENT_Y2018')
ORDER BY TABLE_NAME;
```

```
table_name | tablespace_name
-----+-----
MEASUREMENT | DEFAULT
(1 row)
```

- Support online conversion of regular tables to list type partitioned tables, and synchronously update indexes. see CREATE TABLE.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
CREATE TABLE my_list_tab ( a NUMBER(38,0), cu VARCHAR2(20));
insert into my_list_tab values(1,'china');
insert into my_list_tab values(2,'THAILAND');
insert into my_list_tab values(3,'GERMANY');
insert into my_list_tab values(4,'ITALY');
insert into my_list_tab values(5,'SWITZERLAND');
insert into my_list_tab values(6,'AMERICA');
insert into my_list_tab values(7,'INDIA');
```

```
CREATE INDEX i_a ON my_list_tab (a);
CREATE INDEX i_cu ON my_list_tab (cu);
```

```
ALTER TABLE my_list_tab MODIFY PARTITION BY LIST (cu) (
PARTITION asia VALUES ('CHINA', 'THAILAND'),
PARTITION europe VALUES ('GERMANY', 'ITALY', 'SWITZERLAND'),
PARTITION west VALUES ('AMERICA'),
PARTITION east VALUES ('INDIA'),
PARTITION rest VALUES (DEFAULT))
online
update indexes
( i_a GLOBAL,
i_cu local
);
```

```
\d+ my_list_tab
```

Partitioned table

```
"public.my_list_tab"
Column |      Type      | Collation | Nullable | Default |
Storage | Stats target | Description
-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
a      | numeric(38,0) |          |          |          | main
|          |          |          |          |          |
cu     | varchar2(20)  |          |          |          |
extended |          |          |          |          |
Partition key: LIST (cu)
Indexes:
  "i_a" btree (a)
  "i_cu" btree (cu)
Partitions: "my_list_tab$asia" FOR VALUES IN ('CHINA',
'THAILAND'),
            "my_list_tab$east" FOR VALUES IN ('INDIA'),
            "my_list_tab$europe" FOR VALUES IN ('GERMANY',
'ITALY', 'SWITZERLAND'),
            "my_list_tab$west" FOR VALUES IN ('AMERICA'),
            "my_list_tab$rest" DEFAULT
```

- If (+) is used to join multiple tables in a SELECT query, you can specify the table name for the distinct column in the where condition. see SELECT.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
Create table t1(key1 int, key2 int);
```

```
Create table t2(key1 int);
```

```
Select * from t1, t2 where t1.key1(+)=t2.key1 and key2=2;
  key1 | key2 | key1
-----+-----+-----
(0 rows)
```

- Supports the combination of aggregate count (\*) and order by. see SELECT.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
CREATE TABLE EMP
(  EMPNO      NUMBER(4, 0),
  ENAME      VARCHAR2(10),
  JOB        VARCHAR2(9),
  MGR        NUMBER(4, 0),
  HIREDATE   DATE,
  SAL        NUMBER(7, 2),
  COMM       NUMBER(7, 2),
  DEPTNO     NUMBER(2, 0),
  DNAME      VARCHAR2(100),
  CONSTRAINT PK_EMP PRIMARY KEY (EMPNO)
);
```

```
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7369, 'SMITH', 'CLERK', 7902,
  to_date('1980-12-17', 'yyyy-mm-dd'), 800.00, null, 20, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7499, 'ALLEN', 'SALESMAN', 7698,
  to_date('1981-02-20', 'yyyy-mm-dd'), 1600.00, 300.00, 30, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7521, 'WARD', 'SALESMAN', 7698,
  to_date('1981-02-22', 'yyyy-mm-dd'), 1250.00, 500.00, 30, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7566, 'JONES', 'MANAGER', 7839,
  to_date('1981-04-02', 'yyyy-mm-dd'), 2975.00, null, 20, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7654, 'MARTIN', 'SALESMAN', 7698,
  to_date('1981-09-28', 'yyyy-mm-dd'), 1250.00, 1400.00, 30, null);
```

```
select count(*) from emp order by empno;
  count
-----
      6
(1 row)
```

- connect by supports binding variables. see SELECT.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
PREPARE my_query (VARCHAR) AS
SELECT LEVEL, empno
FROM emp
CONNECT BY PRIOR empno = mgr
START WITH ename = $1;
```

```
EXECUTE my_query('ALLEN');
  level | empno
-----+-----
       1 |  7499
(1 row)
```

- The `merge into` statement supports the branch of the `insert` statement and the use of table aliases. see `MERGE INTO`.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
CREATE TABLE EMP
(  EMPNO      NUMBER(4, 0),
  ENAME       VARCHAR2(10),
  JOB         VARCHAR2(9),
  MGR         NUMBER(4, 0),
  HIREDATE    DATE,
  SAL         NUMBER(7, 2),
  COMM        NUMBER(7, 2),
  DEPTNO      NUMBER(2, 0),
  DNAME       VARCHAR2(100),
  CONSTRAINT PK_EMP PRIMARY KEY (EMPNO)
);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7369, 'SMITH', 'CLERK', 7902,
  to_date('1980-12-17','yyyy-mm-dd'), 800.00, null, 20, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7499, 'ALLEN', 'SALESMAN', 7698,
  to_date('1981-02-20','yyyy-mm-dd'), 1600.00, 300.00, 30, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7521, 'WARD', 'SALESMAN', 7698,
  to_date('1981-02-22','yyyy-mm-dd'), 1250.00, 500.00, 30, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7566, 'JONES', 'MANAGER', 7839,
  to_date('1981-04-02','yyyy-mm-dd'), 2975.00, null, 20, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7654, 'MARTIN', 'SALESMAN', 7698,
  to_date('1981-09-28','yyyy-mm-dd'), 1250.00, 1400.00, 30, null);
```

```

declare
i number;

WHEN MATCHED THEN
    UPDATE SET e.ename = new_data.ename
WHEN NOT MATCHED THEN
    INSERT (e.empno, e.ename) VALUES (
        new_data.empno,
        new_data.ename
    )]';
commit;
end;
/

```

- Added 6 optimizer hints. see `lt_hint_plan`.
- Supported `ignore_row_on_dupkey_index` hint, Prompt: Ignore unique key violations for specific column sets or specified indexes.
- Supported `push_subq` hint. Prompt: Force the optimizer to push down the filter condition of the band link, and only use this condition to filter data at the end.
- Supported `no_push_subq` hint. Prompt: Force the optimizer to push down the filter condition of the band link, and use this condition to filter the data as early as possible.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

create table test_no_push_subq1 as select * from pg_class order
by oid limit 100;
create table test_no_push_subq2 as select * from pg_class order
by oid limit 100;
create table test_no_push_subq3 as select * from pg_class order
by oid limit 100;
create table test_no_push_subq4 as select * from pg_class order
by oid limit 100;

EXPLAIN (COSTS false)
select a.oid from test_no_push_subq1 a join test_no_push_subq3
b on a.reltype =b.reltype and a.oid = b.oid
where a.oid = (select/*+no_push_subq*/ max(oid) from
test_no_push_subq2);

```

QUERY PLAN

```

-----
Hash Join
  Hash Cond: ((a.reltype = b.reltype) AND (a.oid = b.oid))

```

```
Join Filter: (a.oid = $0)
InitPlan 1 (returns $0)
-> Aggregate
    -> Seq Scan on test_no_push_subq2 @"lt#0"
-> Seq Scan on test_no_push_subq1 a @"lt#1"
-> Hash
    -> Seq Scan on test_no_push_subq3 b @"lt#1"
(9 rows)
```

- Supported `opt_param` hint. Prompt: Modify the GUC parameters during the generation of an execution plan.
- Supported `no_star_transformation` hint. Prompt: The optimizer does not perform star query transformations.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle
```

```
CREATE TABLE times (
    time_id NUMBER PRIMARY KEY,
    calendar_quarter_desc VARCHAR2(20)
);
```

```
CREATE TABLE customers (
    cust_id NUMBER PRIMARY KEY,
    cust_city VARCHAR2(20),
    cust_state_province VARCHAR2(20)
);
```

```
CREATE TABLE channels (
    channel_id NUMBER PRIMARY KEY,
    channel_class VARCHAR2(20),
    channel_desc VARCHAR2(20)
);
```

```
CREATE TABLE sales (
    time_id NUMBER REFERENCES times(time_id),
    cust_id NUMBER REFERENCES customers(cust_id),
```

```

channel_id NUMBER REFERENCES channels(channel_id),

amount_sold NUMBER

);

EXPLAIN (COSTS false) SELECT/*+no_star_transformation*/

  -> Seq Scan on test_no_push_pred1 a @"lt#1"
  -> Materialize
      -> Limit
          -> Index Scan using test_no_push_pred2_pkey on
test_no_push_pred2
(6 rows)

```

- Supported `append` hint. Prompt: The optimizer to use direct-path insertion for statements in insert select mode.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

create table test_append(key1 int, key2 int, key3 int, key4
int);
create table test_append1(key1 int, key2 int, key3 int, key4
int);

```

```

insert into test_append1 values(1,2,3,4);
insert into test_append1 values(11,21,31,41);
insert into test_append1 values(111,211,311,411);

EXPLAIN (COSTS FALSE) insert/*+append */ into test_append
  select 1, 1, 1, 2 from dual;
LOG:  lt_hint_plan:
used hint:
not used hint:
append
duplication hint:
error hint:

```

QUERY PLAN

```

-----
Insert on test_append @"lt#1"
  -> Result
(2 rows)

```

- The `to_char` supports HH24MiSS time format. see oraface.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
  oracle;
\c test_oracle

select to_char(timestamp 'now', 'HH24MiSS');
  to_char
-----
  042121
(1 row)

```

- Table functions `column_value` pseudo-columns. see Table function.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
  oracle;
\c test_oracle

create type phone as table of int;
CREATE TYPE

select column_value from table(phone(3,6,9));
  column_value
-----
              3
              6
              9
(3 rows)

```

- Support `pivot` function. Only single clustering functions, single columns and multiple groups are supported. see oraface.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

create table test123(name varchar(40),chinese int,math int,
course varchar(40), score int);
insert into test123 values('lisi',88,99,'math',99);
insert into test123 values('lisi',88,99,'chinese',88);
insert into test123 values('zhangsan',90,100,'chinese',90);
insert into test123 values('zhangsan',90,100,'math',100);

select * from test123 pivot (sum(score) for course
in('chinese','math'));
  name | chinese | math | 'chinese' | 'math'
-----+-----+-----+-----+-----
lisi |      88 |   99 |          88 |      99
lisi |      89 |  100 |           |      99
lisi |     100 |   70 |         100 |
zhangsan |     76 |   89 |          99 |
zhangsan |     90 |  100 |          90 |     100
zhangsan |     95 |   85 |           |     100
(6 rows)

drop table test123;
```

- Merge INTO supports CTE general table expressions. see MERGE INTO.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

CREATE TABLE target (tid integer, balance integer);
CREATE TABLE source (sid integer, delta integer);
INSERT INTO target VALUES (2, 20);
INSERT INTO target VALUES (3, 30);

INSERT INTO source VALUES (1, 11);
INSERT INTO source VALUES (5, 55);

WITH s AS (
    SELECT sid, delta
    FROM source ),
U AS (
UPDATE target AS t
    SET tid = 5
    FROM s
    WHERE t.tid = s.sid
    RETURNING t.tid )
INSERT INTO target (
    SELECT * FROM s where sid NOT IN (
        SELECT tid FROM U) );
```

```

table target;
  tid | balance
-----+-----
    2 |         20
    3 |         30
    5 |         10
    1 |         11
(4 rows)

```

- Immutable tables are supported. see CREATE TABLE.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

CREATE IMMUTABLE TABLE trade_ledger1
    (id NUMBER,
     luser VARCHAR2(40),
     value NUMBER)
NO DROP
NO DELETE;

CREATE TABLE

```

- The group by follows the string constant. see SELECT.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

select * from dual group by 1;
  dummy
-----
    X
(1 row)

```

- Supported alter to add constraints to tables. see ALTER TABLE.

For example:

```

create database test_oracle with lightdb_syntax_compatible_type
oracle;
\c test_oracle

create table add_constraints(id int);

alter table add_constraints add constraint u_add_constraints
unique(id);
ALTER TABLE

```

- Listagg on overflow truncate and error syntax are supported. see see orafce.

- Creating views supports `force editionable` and with `read only` syntax. see `CREATE VIEW`.
- Global temporary tables can be created in different `schema` modes. see `System Catalogs`.
- `varchar2` supports `toast` attributes. see `orafce`.
- The `number` type is formatted without keeping the decimal suffix `invalid 0`. see `orafce`.

For example:

```
create database test_oracle with lightdb_syntax_compatible_type
  oracle;
\c test_oracle

select nvl(cast(NULL as int), '1.100');
nvl
-----
1.1
(1 row)
```

- `dblink` is supported. see `oracle_fdw`.

## E.1.2. plorasql Enhancements

- The number of input and output parameters supported by the function exceeds 100. see `Anonymous Block`.
- The input and exit parameters of the stored procedure that can be created are `sys_refcursor`. see `Creating Cursor Variables`.
- Support for `varray` arrays. see `Varrays`.
- Anonymous blocks, functions, stored procedures, and packages support `integer` types with length information, up to 19 bits. see `Integer Types`.
- Support `execute immediate` using `in out` syntax. see `Executing Dynamic Commands`.

## E.1.3. MySQL Compatibility

- Added `CAST cast` to `SIGNED` or `UNSIGNED` destination type. See `myfce`.

For example:

```
create database test_mysql with lightdb_syntax_compatible_type
  mysql;
\c test_mysql
select cast(2.5 as unsigned);
numeric2unsigned
-----
3
(1 row)

select cast('2.5' as unsigned);
numeric2unsigned
-----
3
(1 row)
```

```
select cast(2.5 as signed);
      signed
-----
          3
(1 row)
```

```
select cast('2.5' as signed);
      signed
-----
          2
(1 row)
```

- Added cast to char target type, The default length of the char is 1, and the number of forcibly converted, the string will not be truncated if the length exceeds 1, and the upper limit is 1GB. See data type.

For example:

```
create database test_mysql with lightdb_syntax_compatible_type
mysql;
\c test_mysql
select cast(2.5 as char);
      varchar
-----
          2.5
(1 row)
```

- Support for comparison of numeric types and null characters. The value of the string is 0. See myfce.

For example:

```
create database test_mysql with lightdb_syntax_compatible_type
mysql;
\c test_mysql
select 0 = '';
      ?column?
-----
          t
(1 row)
```

When characters (including text, varchar, char only) are converted Numeric values (including int, bigint, numeric, small int only), Ignore invalid characters at the trail.

For example:

```
create database test_mysql with lightdb_syntax_compatible_type
mysql;
\c test_mysql
select '1a' > '';
      ?column?
-----
          t
(1 row)
```

- Optimize transform\_null\_equals parameters. Compatible with null and '' relational operations. See myfce.

For example:

```
create database test_mysql with lightdb_syntax_compatible_type
mysql;
\c test_mysql
SELECT '' IS null;
?column?
-----
f
(1 row)

SELECT null = '';
?column?
-----

(1 row)
```

- Time types and strings are supported. See myfce.

For example:

```
create database test_mysql with lightdb_syntax_compatible_type
mysql;
\c test_mysql
select current_date > '2023-01-01';
?column?
-----
t
(1 row)
```

- Add a time type function.
- DATEDIFF function. Support the difference between date and value type, and the difference between value type and value type; When the numeric type is floating-point type, the truncate floating-point type is an integer first, and then the difference is calculated. See myfce.

For example:

```
create database test_mysql with lightdb_syntax_compatible_type
mysql;
\c test_mysql
SELECT DATEDIFF(curdate(),curdate()+1.5);
datediff
-----
-1
(1 row)

SELECT DATEDIFF(curdate(),curdate()-1.5);
datediff
-----
2
(1 row)
```

- `TIMESTAMPDIFF` function. See `myfce`.
- `CURRENT_DATE` function. See `Current Date/Time`.
- `CURDATE` function. The function return format only supports 'YYYY-MM-DD', and does not support multiplication and division. See `myfce`.
- `QUARTER` function. The return date represents the quarter, and the number range is 1 ~ 4. If the date is `NULL`, `NULL` is returned; Input parameters only support `date` and `timestamp (datetime)` types. See `myfce`.
- `LAST_DAY` function. Returns the date value of the last day of the month in which the parameter is located. See `myfce`.
- `SUBSTRING_INDEX` function. Returns the substring from the specified string before the specified delimiter appears `n` times. See `myfce`.
- `UUID` function. Generate a 36-byte `UUID` string. See `myfce`.
- `AES` Encrypt and decrypt. Perform the following AES encryption and decryption and hexadecimal conversion operations. See `myfce`.
  - `HEX` function. The `HEX` function converts `bytea` data to `text`.
  - `UNHEX` function. The `UNHEX` function converts `varchar` data to `bytea`.
  - `AES_ENCRYPT` function. AES encryption functions.
  - `AES_DECRYPT` function. AES decryption function.
- The `time` type supports string assignment. In the `insert` and `update` statements, Values of `type char(n)`, `varchar`, and `text` can be used Assign a value to a property of `type timestamp with time zone, datetime`. See `myfce`.
- Dynamic preprocessing statements are supported.
  - Support `SET` to assign values to `@variables`. See `User Variable`.
  - `PREPARE FROM` preprocessing syntax. See `PREPARE`.

For example:

```
create database test_mysql with lightdb_syntax_compatible_type
mysql;
\c test_mysql
create table my_table(a varchar(200));

SET @sql = 'INSERT INTO my_table values('a')';
        @sql
-----
INSERT INTO my_table values('a')
(1 row)

PREPARE stmt FROM @sql;

EXECUTE stmt;
INSERT 0 1

DEALLOCATE PREPARE stmt;
```

- `WITH ROLLUP` syntax to generate extra rows in the aggregate query for data aggregation. See `GROUP BY`.

For example:

```
create database test_mysql with lightdb_syntax_compatible_type
mysql;
\c test_mysql
CREATE TABLE score (
  id int,
  name varchar(100),
  course varchar(100),
  score int
);
```

```
INSERT INTO score VALUES(1,'zhangsan','yuwen',58);
INSERT INTO score VALUES(2,'lisi','shuxue',38);
```

```
SELECT name, COUNT(id), SUM(score) FROM score GROUP BY name WITH
ROLLUP;
```

name	count	sum
	2	96
lisi	1	38
zhangsan	1	58

(3 rows)

- `CASE WHEN` type compatible. The result set of a `CASE WHEN` expression can be a character, a numeric value, a date. If it contains any two or more characters, values, and dates, the return value is a string. See [Conditional Expressions](#) .
- Numeric types are compatible with Boolean types. The value of the integer type is used as a boolean. See [myfce](#).
- Autoincrement sequences support `NULL`. See [myfce](#).

## E.1.4. Lightdb-x New Features

- Added a record of modifying the `guc` parameter in `lightdb.conf`. See [Parameter Interaction via SQL](#) .
- All types, system tables, and functions are built into the OID unchanged.
- Adjust keyword level. See [SQL Key Words](#) .
- The template library distinguishes between Oracle, MySQL and Postgres patterns. See [CREATE DATABASE](#).

## E.1.5. Itjdbc Enhancements

- Support for converting `numeric` to `varchar`.
- Support for converting `int` to `double`.
- Support `varchar` conversion to `long`.
- Support for converting `timestampz` to `java.time.LocalDateTime`.
- Anonymous block parameter binding is supported, and the maximum number of bindings is 32767.
- The `clob.setCharacterstream` function is supported.
- The `getColumnType` method of `metaData` returns the `varchar2` type.
- Primary key conflict throws an anomaly of `java.sql.SQLIntegrityConstraintViolationException`
- The binding parameters are passed with `setNull`, and the types can be matched correctly.

## E.1.6. Add Reserved Keywords

- pivot.

## E.2. Release 13.8-23.3

Release date: 2023-09-30

### E.2.1. Oracle Compatibility

- The `CREATE SEQUENCE` command supports declaring `NOMAXVALUE` when creating a sequence, which is compatible with the `NOMAXVALUE` definition when creating a sequence in Oracle. See `CREATE SEQUENCE`.

Example:

```
create sequence s1 nomaxvalue;
\d+ s1
Sequence "public.s1"
Type | Start | Minimum | Maximum | Increment |
Cycles? | Cache
-----+-----+-----+-----+-----+-----
+-----+-----
bigint | 1 | 1 | 9223372036854775807 | 1 | no
| 1
```

- The `CREATE SEQUENCE` command supports declaring `MAXVALUE` when creating a sequence, which is compatible with the `MAXVALUE` definition when creating a sequence in Oracle. See `CREATE SEQUENCE`.

Example:

```
create sequence s2 maxvalue 100000;
\d+ s2
Sequence "public.s2"
Type | Start | Minimum | Maximum | Increment | Cycles? | Cache
-----+-----+-----+-----+-----+-----+-----
+-----+-----
bigint | 1 | 1 | 100000 | 1 | no | 1
```

- The `CREATE TABLE` command supports the `nocompress/compress` keywords when creating partitions. See `CREATE TABLE`.

Example:

```
CREATE TABLE lt_oracle_partition_list1
(
  a int,
  b float,
  c date,
  d timestamp,
  e varchar2(20)
) PARTITION BY LIST(e)
```

```
(
  PARTITION p1 VALUES ('0001', '0002', '0003', '0004', '0005')
  compress,
  PARTITION p2 VALUES ('0006', '0007', '0008', '0009')
  nocompress,
  PARTITION p3 VALUES ('0010', '0011')
);
\d+ lt_oracle_partition_list1
```

Partitioned table "public.lt\_oracle\_partition\_list1"

Column	Type	Collation	Nullable
Default	Storage	Stats target	Description
a	integer		
	plain		
b	double precision		
	plain		
c	oracle.date		
	plain		
d	timestamp without time zone		
	plain		
e	varchar2(20)		
	extended		

Partition key: LIST (e)

Partitions: "lt\_oracle\_partition\_list1\$p\$p1" FOR VALUES IN ('0001', '0002', '0003', '0004', '0005'),  
 "lt\_oracle\_partition\_list1\$p\$p2" FOR VALUES IN ('0006', '0007', '0008', '0009'),  
 "lt\_oracle\_partition\_list1\$p\$p3" FOR VALUES IN ('0010', '0011')

- The CREATE TABLE command supports creating partitions using a list+hash composite partition. See CREATE TABLE.

Example:

```
create table lt_lh_partition(a int, b int)
partition by list(a)
subpartition by hash(b)
(
  partition l_1 values(1),
  partition l_2 values(2)
);
```

```
\d+ lt_lh_partition
```

Partitioned table "public.lt\_lh\_partition"

Column	Type	Collation	Nullable	Default	Storage
Stats target	Description				
a	integer				plain
b	integer				plain

Partition key: LIST (a)

```

Partitions: "lt_lh_partition${p$1}_1" FOR VALUES IN (1),
PARTITIONED,
"lt_lh_partition${p$1}_2" FOR VALUES IN (2), PARTITIONED

\d+ lt_lh_partition${p$1}_1

Partitioned table "public.lt_lh_partition${p$1}_1"
Column | Type | Collation | Nullable | Default | Storage |
Stats target | Description
-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
a | integer | | | | plain |
| | | | | | |
b | integer | | | | plain |
| | | | | | |
Partition of: lt_lh_partition FOR VALUES IN (1)
Partition constraint: ((a IS NOT NULL) AND (a = 1))
Partition key: HASH (b)
Partitions: "lt_lh_partition${p$1}_1_p0" FOR VALUES WITH (modulus
1, remainder 0)

```

- The `CREATE TABLE` command supports options such as `compress/nocompress` and `logging/nologging`. Previous versions had order restrictions for these options, but this version allows them to appear in arbitrary order. See `CREATE TABLE`.
- It is not allowed to have the same table name as a package name when creating a table using `CREATE TABLE` and when creating a package using `CREATE PACKAGE`.
- The `ALTER TABLE` command supports adding multiple columns at once by placing the column definitions in parentheses. See `ALTER TABLE`.

Example:

```

CREATE TABLE foo(a int);
ALTER TABLE foo ADD COLUMN a1 int;
ALTER TABLE foo ADD COLUMN a2 int default 3;
ALTER TABLE foo ADD COLUMN b1 int, ADD COLUMN b2 int;
ALTER TABLE foo ADD (c1 int);
ALTER TABLE foo ADD (c2 int default 3);
ALTER TABLE foo ADD (e1 int), ADD e2 int, ADD COLUMN e3 int, ADD
(e4 int, e5 int);
begin
execute immediate 'alter table foo add(d int)';
end;
/

```

- The `ALTER TABLE` command supports the `TRUNCATE PARTITION partition_name` statement with the `update indexes` specified. See `ALTER TABLE`.

Example:

```

create table part_update_indexes_range(id int primary key)
PARTITION by range(id)(
partition p1 VALUES LESS THAN (202000) nocompress,
partition p2 VALUES LESS THAN (202001) compress,
partition p3 VALUES LESS THAN (202002)

```

```
);
```

```
ALTER TABLE part_update_indexes_range TRUNCATE PARTITION p1
update indexes;
```

- The `DROP TABLE` command supports cascading the deletion of all constraints in the table using the `cascade constraints` option. See `DROP TABLE`.

Example:

```
CREATE TABLE student(id int, name varchar2(100));
```

```
ALTER TABLE student ADD CONSTRAINT uk_student unique(id);
```

```
\d student
```

```
Table "public.student"
```

Column	Type	Collation	Nullable	Default
id	integer			
name	varchar2(100)			

```
Indexes:
```

```
"uk_student" UNIQUE CONSTRAINT, btree (id)
```

```
DROP TABLE student cascade constraints;
```

- A new syntax has been added for creating object types using `CREATE TYPE name { AS | IS } OBJECT`. See `CREATE TYPE`.

Example:

```
select dbms_output.serveroutput(true);
CREATE TYPE stock AS OBJECT (
    stock_no int,
    price    numeric(16,2),
    member procedure dis(prompt varchar)
);
```

```
CREATE TYPE BODY stock AS
    member procedure dis(prompt varchar) is
    begin
        dbms_output.put_line(prompt || ':' || self.stock_no ||
        '-' || self.price);
    end;
END;
/
```

```
DECLARE
    s stock := stock(600570, 180.00);
BEGIN
    s.dis('current');
END;
/
```

```
current:600570-180.00
DO
```

- A new TO\_CLOB function has been added, which allows converting data from a text string type to a CLOB type. See orafce.

Example:

```
CREATE TABLE testorafce_to_clob (  
    col_char CHAR(10),  
    col_varchar2 VARCHAR2(20),  
    col_varchar VARCHAR(20),  
    col_nchar NCHAR(10),  
    col_nvarchar2 NVARCHAR2(20),  
    col_smallint smallint,  
    col_integer integer,  
    col_bigint bigint,  
    col_decimal decimal,  
    col_numeric numeric,  
    col_real real,  
    col_double double precision,  
    col_clob CLOB,  
    col_raw raw(10)  
);  
  
INSERT INTO testorafce_to_clob (col_char, col_varchar2,  
    col_varchar, col_nchar, col_nvarchar2, col_smallint,  
    col_integer, col_bigint, col_decimal, col_numeric, col_real,  
    col_double, col_clob, col_raw)  
VALUES ('ABC1', 'Hello', 'world', 'hello', 'world', 1, 2, 3, 4,  
    5, 6, 7, 'This is a CLOB', 'AB');
```

```
INSERT INTO testorafce_to_clob (col_char, col_varchar2,  
    col_varchar, col_nchar, col_nvarchar2, col_smallint,  
    col_integer, col_bigint, col_decimal, col_numeric, col_real,  
    col_double, col_clob, col_raw)  
VALUES ('ABC2', 'Hello', 'world', 'hello', 'world', 1, 2, 3, 4,  
    5, 6, 7, 'This is a CLOB', '1');
```

```
INSERT INTO testorafce_to_clob (col_char, col_varchar2,  
    col_varchar, col_nchar, col_nvarchar2, col_smallint,  
    col_integer, col_bigint, col_decimal, col_numeric, col_real,  
    col_double, col_clob, col_raw)  
VALUES ('ABC3', 'Hello', 'world', 'hello', 'world', 1, 2, 3, 4,  
    5, 6, 7, to_clob('This is a CLOB'), '1AB456789');
```

```
SELECT to_clob(col_char) AS clob_char,  
to_clob(col_varchar2) AS clob_varchar2,  
to_clob(col_varchar) AS col_varchar,  
to_clob(col_nchar) AS clob_nchar,  
to_clob(col_nvarchar2) AS clob_nvarchar2,  
to_clob(col_clob) AS clob_clob,  
to_clob(col_smallint) AS col_smallint,  
to_clob(col_integer) AS col_integer,  
to_clob(col_bigint) AS col_bigint,  
to_clob(col_decimal) AS col_decimal,  
to_clob(col_numeric) AS col_numeric,  
to_clob(col_real) AS col_real,
```

```

to_clob(col_double) AS col_double,
to_clob(col_raw) AS clob_nclob
FROM testorafce_to_clob order by col_char asc;

```

```

clob_char | clob_varchar2 | col_varchar | clob_nchar |
clob_nvarchar2 | clob_clob | col_smallint | col_integer |
col_bigint | col_decimal | col_numeric | col_real | col_double |
clob_nclob
-----+-----+-----+-----+
+-----+-----+-----+-----+
+-----+-----+-----+-----+
+-----+
ABC1      | Hello          | world        | hello        | world
          | This is a CLOB | 1            | 2            | 3
          | 4              | 5            | 6            | 7            | AB
ABC2      | Hello          | world        | hello        | world
          | This is a CLOB | 1            | 2            | 3
          | 4              | 5            | 6            | 7            | 01
ABC3      | Hello          | world        | hello        | world
          | This is a CLOB | 1            | 2            | 3
          | 4              | 5            | 6            | 7            | 01AB456789
(3 rows)

```

- A new XMLType object type has been added, which supports the XMLType.getClobVal method. See orafce.

Example:

```

CREATE TABLE xml_table (id NUMBER, xml_column XMLType );

INSERT INTO xml_table (id, xml_column) VALUES (1,
XMLType('<root><name>John</name></root>'));

DECLARE
    v_clob CLOB;
BEGIN
    SELECT XMLType.getClobVal(xml_column) INTO v_clob FROM
xml_table WHERE id = 1;
    DBMS_OUTPUT.PUT_LINE('CLOB value: ' || v_clob);
END;
/
CLOB value: <root><name>John</name></root>
DO

DECLARE
    xml_data XMLType;
    clob_data CLOB;
BEGIN
    xml_data := XMLType('<root><name>John Doe</name></root>');
    clob_data := xml_data.getClobVal();
    DBMS_OUTPUT.PUT_LINE(clob_data);
END;
/
<root><name>John Doe</name></root>
DO

```

```
SELECT XMLType.getClobVal(xml_column) from xml_table;
getclobval
-----
<root><name>John</name></root>
(1 row)
```

- A new GUC parameter `lightdb_oracle_sql_mode` has been added to support the default conversion of Oracle mode table names to uppercase. See `lightdb_oracle_sql_mode`.

Example:

```
create table std(no int, name varchar2(32));

insert into std values(1, 'zhangsan');

select * from std;
no | name
----+-----
1 | zhangsan
(1 row)

set lightdb_oracle_sql_mode to 'true';

select * from std;
NO | NAME
----+-----
1 | zhangsan
(1 row)
```

- The `ltsql` command has added support for the Oracle SQL\*Plus `RENAME old_name TO new_name` command, which allows renaming tables. See `RENAME` command.
- The `ltsql` command has added support for the Oracle SQL\*Plus `SPOOL` command. See `SPOOL` command.
- In Oracle mode, support is added for `binary_float` and `binary_double`, both of which follow the IEEE754 standard. See `orafce`.
- In Oracle mode, `'\0'` can be inserted normally into `char(n)` type strings.

Example:

```
create database oradb with lightdb_ascii_zero_store_value 20
  lightdb_syntax_compatible_type 'oracle';
\c oradb

create table t00(a char(1), b char(2));

insert into t00(a,b) values(E'\0',E'\0');

insert into t00(a,b) values(chr(0),chr(0));

select * from t00;
```

```

a   |   b
-----+-----
\x14 | \x14
\x14 | \x14
(2 rows)

```

'\0' is converted to the `lightdb_ascii_zero_store_value` value for storage.

- In Oracle mode, the result of subtracting dates is compatible with Oracle and returns a numeric type.
- The `col` view is compatible with Oracle, and the width field remains compatible with Oracle.
- `greatest/least` are compatible with Oracle. See `GREATEST` and `LEAST`.

The following compatibility features have been mainly implemented:

Returns `NULL` if there is a `NULL` parameter.

The types of the remaining parameters are forced to convert to the type of the first parameter.

If a `NULL` parameter is encountered, parsing of the remaining parameters is stopped.

- All Oracle functions in `orafce` are now default safe, and parallel processing is enabled by default.

## E.2.2. plorasql Enhancements

- PL/oraSQL functions support transaction commit and rollback. See Enhancements for Oracle.
- PL/oraSQL functions support `inout` parameters. See Declaring Function Parameters.
- PL/oraSQL functions support DML statements. See Executing DML in PL/oraSQL.
- PL/oraSQL stored procedures support the use of `CREATE DOMAIN` to create cursor type variables.

Example:

```

SELECT dbms_output.serveroutput(true);
CREATE TABLE employees(employee_id int, first_name varchar2(100),
  last_name varchar2(100));
INSERT INTO employees values(1500, 'first15', 'last15');
CREATE DOMAIN mycursor AS refcursor;
CREATE OR REPLACE PROCEDURE get_employee_name AS
  employee_cursor mycursor;
  v_employee_name VARCHAR2(50);
BEGIN
  OPEN employee_cursor FOR SELECT first_name FROM employees
  WHERE employee_id = 1500;
  LOOP
    FETCH employee_cursor INTO v_employee_name;
    EXIT WHEN employee_cursor%NOTFOUND;
    DBMS_OUTPUT.PUT_LINE('Employee Name: ' ||
  v_employee_name);
  END LOOP;
  CLOSE employee_cursor;
END;
/
call get_employee_name ();
Employee Name: first15

```

CALL

## E.2.3. MySQL Compatibility

- New `INSERT IGNORE` functionality. See `INSERT` for more information.

Example:

```
create database test_mysql with lightdb_syntax_compatible_type
mysql;
\c test_mysql
```

```
create table t(a int primary key, b int);
insert ignore into t(a,b) values(1,1),(1,1),(2,2);
select * from t;
```

```
a | b
---+---
1 | 1
2 | 2
(2 rows)
```

- A new collection of `JSON` functions has been added. See `myfce JSON` functions for more information. The list of functions is as follows:

`JSON_ARRAY`

`JSON_OBJECT`

`JSON_EXTRACT`

`JSON_CONTAINS`

`JSON_CONTAINS_PATH`

`JSON_PRETTY`

`JSON_REMOVE`

`JSON_INSERT`

`JSON_REPLACE`

`JSON_SET`

- A new parameter `lightdb_mysql_lower_case_table_names` has been added. When creating a database using the `create database` statement, you can specify this parameter to set whether case-sensitive functionality is enabled. See `CREATE DATABASE` for more information.
- The `varchar` type is compatible with `boolean` type data. See `myfce` for more information.

## E.2.4. Lightdb-x New Features

- A new upgrade check tool called `lt_upgrade_check` has been added to perform compatibility and exception checks before upgrading, in order to minimize the possibility of upgrade failures. See `lt_upgrade_check` for more information.
- Support for using `'-'` and `'//'` comments has been added to `ECPG` code. See `ECPG` for more information.
- New support for GBK, GB18030-2022 on both server and client sides has passed the national standard certification of the People's Bank of China. See `localization` for details.

- The new behavior of `lt_createdb` is to propagate to DN nodes by default in a CN distributed environment. See `lt_createdb` for more information.
- A new GUC parameter called `lightdb_cursor_after_commit` has been added to control fetch behavior. When `lightdb_cursor_after_commit` is set to `off`, fetch operations cannot be performed on a result set after a transaction commit. When set to `on`, the cursor can continue to be used after a transaction commit. See `lightdb_cursor_after_commit` for more information.
- Added support for the `distinct connect by level` syntax.
- Added support for the `connect_by_isleaf` syntax. See `SELECT` for more information.
- Enhanced support for displaying the compatibility mode of the current service database in `ltsql`.
- Enhanced support for cross-version upgrades in `lt_upgrade`.
- `ltloader` enhances performance to over 80% of Oracle's `sqlldr`. See `ltldr` for more information.
- Enhancements have been made to `lt_dump`. See `lt_dump` for more information. The enhancements include:

The `--lt-exclude-lightdb-objects` option supports filtering out built-in users `lightdb` and `lt_probackup`.

The `--lt-exclude-lightdb-objects` option supports exporting `ACCESS METHOD`.

Both `lt_dump` and `lt_dumpall` have added the `--lt-target-version` option, which allows you to specify the target version for the exported content.

The default template for exporting is now `templatel`.

The `create database` statement now supports the `lightdb_syntax_compatible_type` option logic.

- Enhanced support for querying fields larger than 64K has been added to `mysql_fdw`.

## E.2.5. Itjdbc Enhancements

- `ltjdbc` supports numeric with `Short` type.
- `ltjdbc` supports passing `Types.CLOB` and `Types.BLOB` to `setNull` function.
- `ltjdbc` supports using `string` type for integer values.
- `ltjdbc` supports the function `xmlparse`.

## E.3. Release 13.8-23.2

Release date: 2023-06-30

### E.3.1. Oracle Compatibility

- The `CHAR` data type now supports specifying byte or character lengths. When defining a column in a table using the `CHAR` data type, you can now specify the length of the column value, which can be either byte length or character length. See `Character Types`.

For example:

```
create table t (id char (1 char));
create table t (id char (1 byte));
```

- The hierarchical query has been enhanced to include new features such as `CONNECT_BY_ROOT`, which displays the root node of the current row, and `CONNECT BY LEVEL < n`, which displays all recursive results up to a specified level `n`. Additionally, hierarchical queries now support subqueries, join queries, and expression calculations. See `CONNECT BY Clause`.

For example:

```

SELECT employee, CONNECT_BY_ROOT employee_id as "Manager",
SYS_CONNECT_BY_PATH(employee, '/') "Path"
FROM example
START WITH manager_id is not null
CONNECT BY PRIOR employee_id = manager_id
ORDER BY employee_id, manager_id;
  employee | Manager | Path
-----+-----+-----
  Josh     |        | /Josh
  Ali      |        | /Ali
  Ali      |        | /Josh/Ali
  Kyle     |        | /Kyle
(4 rows)

```

- The ALTER TABLE command has been enhanced to support deleting indexes and constraints on the same column. See ALTER TABLE.

For example:

```

ALTER TABLE my_table
DROP CONSTRAINT my_constraint,
DROP INDEX my_index;

```

- Support the use of the + symbol to represent LEFT JOIN and RIGHT JOIN. See oracle plus.

For example:

```

SELECT *
FROM table1, table2
WHERE table1.id = table2.id (+);

```

- USING INDEX clause is now supported in CREATE TABLE and ALTER TABLE statements to specify an index to support a constraint. See ALTER TABLE.

For example:

```

ALTER TABLE employees
ADD CONSTRAINT emp_id_pk
PRIMARY KEY (id)
USING INDEX;

```

- FROM is now optional in DELETE statements. See DELETE.

For example:

```

DELETE table_name WHERE col = 1;

```

- SYS.COL system view is now available to display columns information for all tables, including column name, data type, length, precision, nullability, default value, and character set name. See orafce.

For example:

```
create table test_col_view(key0 varchar(100), key1 number not
null, key2 number(38,0));

select * from col where tname= 'TEST_COL_VIEW' order by colno;
  tname      | colno | cname | coltype | width | scale |
precision | nulls  | defaultval | character_set_name
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
TEST_COL_VIEW |      1 | KEY0  | VARCHAR | 100   |       |
| NULL      |       |       |         |       |       |
TEST_COL_VIEW |      2 | KEY1  | NUMBER  |       |       |
| NOT NULL  |       |       |         |       |       |
TEST_COL_VIEW |      3 | KEY2  | NUMBER  | 38,0  | 0     |
38 | NULL      |       |         |       |       |
(3 rows)
```

- INSERT ALL syntax is now supported for inserting multiple rows into one or more tables in a single statement. See INSERT.

For example:

```
INSERT ALL
  INTO table_name (column1, column2, column3) VALUES (value1,
value2, value3)
  INTO table_name (column1, column2, column3) VALUES (value1,
value2, value3)
SELECT 1 FROM DUAL;
```

- INSERT INTO statement now supports using aliases to specify the table to insert data into. See INSERT.

For example:

```
INSERT INTO employees e (employee_id, first_name, last_name)
VALUES (1001, 'John', 'Doe');
```

- MERGE INTO statement now supports distributed scenarios. See MERGE INTO.

For example:

```
MERGE INTO target t
USING source s
ON t.tid = s.sid
WHEN MATCHED THEN
  update set balance = t.balance + s.delta
WHEN NOT MATCHED THEN
  INSERT VALUES(s.sid, s.delta);
```

- Support implicit type conversion for NUMBER and BOOLEAN data types. See orafce.

For example:

```
select 0::NUMBER = TRUE;
?column?
-----
f
(1 row)
```

```
select 1::NUMBER = TRUE;
?column?
-----
t
(1 row)
```

- Partitioned tables are now more compatible with Oracle, as they support both Oracle-compatible partition naming and operations on subpartitions. See ALTER TABLE.

For example:

```
alter table lt_truncate_t_r truncate partition p1;
alter table lt_truncate_t_r add partition p2 values less
than(30);
alter table lt_truncate_t_r truncate partition p2;
alter table lt_truncate_t_r drop partition p2;
```

- CREATE TABLE now supports the STORAGE, compress / nocompress, and logging / nologging keywords, although these are only syntactic sugar and do not provide actual functionality. See CREATE TABLE.

For example:

```
create table comp_log1(id int) compress;
create table comp_log3(id int) logging;
create table comp_log5(id int) compress logging;
create table comp_log13(id int) storage(abcd);
```

- PROMPT command is now supported to display text messages to users. See prompt command.

For example:

```
PROMPT Creating table...

CREATE TABLE test_table (
  id NUMBER PRIMARY KEY,
  name VARCHAR2(50)
);

PROMPT Inserting data...

BEGIN;
INSERT INTO test_table (id, name) VALUES (1, 'John Doe');
INSERT INTO test_table (id, name) VALUES (2, 'Jane Smith');
COMMIT;

PROMPT Querying data...
```

```
SELECT * FROM test_table;
DROP table test_table;
PROMPT Done.
```

- ALTER INDEX now supports the REBUILD keyword to rebuild a specific index. See ALTER INDEX.

For example:

```
CREATE TABLE tt(a int);
CREATE INDEX idx_tt_a on tt(a);
ALTER INDEX idx_tt_a REBUILD;
```

- SEQUENCE statement now supports order / noorder / nocycle / nocache keywords, although these are only syntactic sugar and do not provide actual functionality. See CREATE SEQUENCE.

For example:

```
create sequence lt_seq_test1 order start 100;
create sequence lt_seq_test3 start 100 nocycle;
create sequence lt_seq_test5 start 100 ORDER nocache NOCYCLE;
alter sequence lt_seq_test1 nocache nocycle noorder;
```

- CREATE FORCE VIEW statement is now supported, although this is only syntactic sugar and does not provide actual functionality. See CREATE VIEW.

For example:

```
CREATE FORCE VIEW force_view as SELECT 1 as ltapk, 2 as ltaut;
```

- ECPG now supports anonymous execution blocks with binding parameters. See Executing a Do Statement with Input and Output Parameters.

For example:

```
EXEC SQL EXECUTE
begin
begin
update/*3631412*/ t1 set c = 'C' where id = :v_error_no;
exception
when others then
:iReturnCode = 456;
rollback;
when DUP_VAL_ON_INDEX then
null;
if SQL%NOTFOUND then
null;
end if;

end;
end;
```

---

```
END-EXEC;
```

## E.3.2. plorasql Enhancements

- Added support for `sqlcode` in `plorasql`. Users can now create functions that return `sqlcode` values like in Oracle. See support `SQLCODE`.

For example, the following code will output the SQL error code when a zero divide error occurs:

```
create or replace function zero_divide_f return int as
  a int := 10;
  b int := 0;
  code int;
begin
  a := a / b;
  exception
    when zero_divide then
      code := sqlcode;
      dbms_output.put_line('this is a normal error ' || code
|| ' ' || sqlcode || 'sqlcode_to_sqlstate(code) || ' ' ||
sqlcode_to_sqlstate(sqlcode));
      return 1;
end;
/
```

- Added support for the `with` clause in `plorasql`. Users can now use the `with` clause to define temporary result sets within a single SQL statement. See `Execute a DML Query with with_clause`.

For example:

```
declare
  v_count varchar(100);
begin
  with tmp as (select * from company where id=2) select * into
v_count from tmp;
  DBMS_OUTPUT.PUT_LINE(v_count);
end;
/
```

- Added support for parsing the `PRAGMA AUTONOMOUS_TRANSACTION` syntax in `plorasql`. Note that this is a syntax sugar feature and does not implement the actual functionality in Oracle. See `AUTONOMOUS TRANSACTION Pragma`.

For example:

```
CREATE OR REPLACE PROCEDURE test_pragma_procedure()
IS
  PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
  NULL;
END;
/
```

- Enabled case-insensitive cursor variable names in plorasql. This means that users can now use cursor variable names with different capitalizations than when they were declared without causing syntax errors. See Cursors .

For example:

```
DECLARE
  CURSOR D_tmp(zxc NUMBER,bnm NUMBER,ff smallint default 1234) IS
    SELECT ff || a as feiwu FROM tt;
  ddd D_tmp%ROWTYPE;
BEGIN
  OPEN D_tmP(5,6);
  FETCH d_tmp INTO ddd;
  DBMS_OUTPUT.PUT_LINE(ddd.feiwu);
  CLOSE D_tmP;
end;
/
```

- Added support for referencing the type of a variable defined in a package using the %TYPE syntax in plorasql. See Declarations .

For example:

```
create table t_binjiang(a int, b int);
-- define package
create or replace package pkgtype is
  v_a int := 0;
  v_b int := 0;
end;
/

-- anonymous block references variables in the package
declare
  a pkgtype.v_a%type := 1;
  b pkgtype.v_b%type := 1;
begin
  insert into t_binjiang values(a, b);
end;
/
```

- Added support for the goto statement in plorasql. Users can now use the goto statement to jump to a specific label within a block. See GOTO Statement .

For example:

```
DO $$
BEGIN
  RAISE NOTICE 'out block 1';
  goto testlabel;
  RAISE NOTICE 'out block 2';
  <<testlabel>>
  BEGIN
    RAISE NOTICE 'in block 1';
    goto testlabel2;
  END;
END;
```

```

        RAISE NOTICE 'in block 2';
    END;

    RAISE NOTICE 'out block 3';

    <<testlabel2>>
    RAISE NOTICE 'out block 4';

END$$;
NOTICE:  out block 1
NOTICE:  in block 1
NOTICE:  out block 4

```

- Enabled the ability to call package functions in distributed scenarios in plorasql. See Packages .

For example:

```

create or replace package typkg
as
    type nt is table of tabl%rowtype;
    res nt;
    function myfunc(v int) return nt;
end;
/

create or replace package body typkg
as
    function myfunc(v int) return nt
    is
    begin
        res(1) := ROW(1,1);
        res(2) := ROW(2,2);
        res(3) := ROW(3,3);
        return res;
    end;
end;
/

select * from table(typkg.myfunc(1)) t0
where t0.a in (select a from tabl) order by t0.a;

```

### E.3.3. MySQL Compatibility

- Supports `DROP INDEX [IF EXISTS] index_name ON table_name`; See `DROP INDEX` .

For example:

```

create table t1(id int);
create unique index idx_t1_id on t1(id);
drop index idx_t1_id on t1;

```

- Case-insensitive column querying and case-sensitive column display. In `mysql` mode, `guc` parameter `lightdb_sql_mode` is set to `uppercase_identifier`. See `SELECT` .

For example:

```
create table test_case_1(identifier1 varchar(10));

select * from test_case_1;
identifier1
-----
(0 rows)

select Identifier1 from test_case_1;
Identifier1
-----
(0 rows)

select identifier1 as Identifier1 from test_case_1;
Identifier1
-----
(0 rows)
```

- Supports `INSERT IGNORE INTO` syntax. `INSERT IGNORE INTO` statement is used to insert data into a table. If the inserted data violates uniqueness constraints such as primary key or unique index, the data will be ignored without throwing any errors or warnings. See `INSERT` .

For example:

```
INSERT IGNORE INTO table_name (column1, column2, column3, ...)
VALUES (value1, value2, value3, ...);
```

- Supports adding comments to database objects (such as tables, columns, etc.) using the `COMMENT` keyword. See `CREATE TABLE` .

For example:

```
create table t1 (
    id int primary comment 'this is id of t1' not null,
    name varchar(10) not null comment 'this is name of t1'
) comment = 'this is t1';
```

- Supports JSON-related functions. See `myfnc` .

`JSON_ARRAY`: creates a JSON array.

`JSON_OBJECT`: creates a JSON object.

`JSON_EXTRACT`: extracts values from JSON data.

`JSON_CONTAINS`: checks whether JSON data contains the specified value.

`JSON_CONTAINS_PATH`: checks whether the specified path exists in JSON string.

`JSON_PRETTY`: a function used to format JSON string. It takes an unformatted JSON string as input and formats it into an easy-to-read form.

- Supports `sysdate()` function for retrieving the current execution time. See `Current Date/Time` .

For example:

```
select sysdate();
       sysdate
-----
2023-05-09 13:21:13
(1 row)
```

- Fixed the issue of dual virtual table in mysql mode, which caused unauthorized access for ordinary users. See `myfce` .

For example:

```
create user mytestuser with password 'mytestuser';
\c - mytestuser

select 2 from dual;
?column?
-----
          2
(1 row)
```

## E.3.4. Lightdb-x New Features

- PWR accurately measures real-time query IO events, IPC events, race conditions and other time overhead, and optimizes the performance report statistics of PWR. See `lt_profile` .
- `lt_hint_plan` optimizes scenarios that do not support hints and ignores unimplemented hints. See `lt_hint_plan` .
- Supports incremental checkpoint to reduce the performance impact on the database system when triggering checkpoints. See `CHECKPOINT` .
- Supports debugging PL/pgsql stored procedures in pgadmin/navicat. See `pldebugger` .
- PL/pgsql supports `execute immediate` syntax. Note that this is only a syntax sugar feature and does not implement the corresponding functionality. See `Executing Dynamic Commands` .

For example:

```
CREATE OR REPLACE FUNCTION get_employee_name_func(p_employee_id
INTEGER)
RETURNS VARCHAR AS $$
DECLARE
    sql_query TEXT;
    emp_name VARCHAR;
BEGIN
    sql_query := 'SELECT first_name FROM test_employees WHERE
employee_id = $1';
    EXECUTE IMMEDIATE sql_query INTO emp_name USING
p_employee_id;

    RAISE NOTICE 'Employee name is: %', emp_name;
    RETURN emp_name;
END;
$$ LANGUAGE plpgsql;
```

- Released a client package. After extracting and configuring the environment variables, users can directly use the relevant tools, including the following tools:

`lt_distributed_probackup.py`

`lt_distributed_dump.py`

`lt_distributed_restore.py`

`ltuldr`

`lt_basebackup`

`lt_dump`

`lt_dumpall`

`lt_isready`

`lt_probackup`

`lt_restore`

`lt_verifybackup`

`ltsql`

### E.3.5. Itjdbc Enhancements

- Added support for reading BLOB values in the form of byte arrays using the `java.sql.ResultSet #getBlob (java.lang.String)` method. See LightDB JDBC .
- Added support for executing SQL statements to create stored procedures and functions using syntax such as `CREATE PROCEDURE` and `CREATE FUNCTION` in the Itjdbc library. See LightDB JDBC .
- Added support for converting date column types to `LocalDateTime` objects using the `java.sql.ResultSet#getObject(int, java.lang.Class<T>)` method. See See LightDB JDBC .

## E.4. Release 13.8-23.1

Release date: 2023-03-30

### E.4.1. New feature

- Out of memory problems occur when memory is allocated, add detail and hint hints.
- LightDB supports kubernetes(K8S) HA deployment,. The core modules include `LightDB-patroni` image and `LightDB-operator` image. `LightDB-patroni` image contains `LightDB` and `Patroni` for support HA deployment in container. `LightDB-operator` image are used to manage `LightDB` cluster in kubernetes.
- Added `guc` parameter `lightdb_server_version_num` to identify the `LightDB` version number. This value cannot be modified at the session level, in the `lightdb.conf` configuration file. see `SHOW`.

Show lightdb server version number:

```
SHOW lightdb_server_version_num;
lightdb_server_version_num
-----
220400
(1 row)
```

- Added extension `lt_sql_inspect` to define transaction hours, as well as intercept and audit execution of dangerous SQL and commands during trading hours. see `lt_sql_inspect`.

## E.4.2. Optimize

`lt_probackup` supports distributed optimization. see `lt_distributed_probackup`.

- Added distributed backup ids in the script.
- You can view the overall status of backups by distributed backup id.

## E.4.3. Compatibility

### E.4.3.1. MySQL compatible

- Supports functions `substr` and `substring`. see function.

for example:

```
lightdb@postgres=# create database test_createdb_mysql with
lightdb_syntax_compatible_type mysql;
CREATE DATABASE
lightdb@postgres=# \c test_createdb_mysql
You are now connected to database "test_createdb_mysql" as user
"lightdb".
lightdb@test_createdb_mysql=# select substr('sadayertyui',-3,3)
FROM DUAL;
substr
-----
yui
(1 row)
```

- Support MySQL division, including integer division by integer, division by 0 operation, etc see `myfce`.

for example:

```
lightdb@test_createdb_mysql=# select 4/0;
WARNING: division by zero
?column?
-----

(1 row)
lightdb@test_createdb_mysql=# select 4/1;
?column?
-----
4.0000000000000000
(1 row)
```

- Support for `str_to_date` function. see `myfce`.

- Prepare statements are not supported for variable binding.
- Due to the use of Julian days to express time, it is impossible to express the illegal date of 1999-00-00.
- The `lightdb_sql_mode` value is `no_zero_date`, and the return value is an empty string, not NULL.
- Illegal date error is reported, using LightDB error reporting logic.

for example:

```
select str_to_date('2022/09/10 11,13,13', '%Y/%m/%d %h,%i,%s');
      str_to_date
-----
      2022-09-10 11:13:13
(1 row)
```

- Support for @ variables. see User Variable.
  - If the variable is not initialized, the type of the variable is `text`.
  - If the variable type is `float`, `float8`, the storage type is `float8`.
  - If the value of the variable is an integer type (`smallint`, `bigint`, `int`), the storage type is `bigint`.
  - If the type of the variable is `numeric`, the storage type is `numeric`.
  - If the variable type is another type, the variable type is `text`.

User variables are written as `@var_name`, where the variable name `var_name` must be an Identifiers or an Key Words. If you quote it identifier#var\_name will be treated as a column name (for example, `@"my-var"`). `@var_name` and `@ var_name` are different. `@var_name` is a user variable expression, `@ var_name` is the absolute value of the column `var_name`.

```
lightdb@test=# select @c1 := 5;
      @c1
-----
      5
(1 row)

lightdb@test=# SELECT c1, @c1, @ c1 FROM t;
 c1 | @c1 | ?column?
-----+-----+-----
  0 |  5 |          0
  1 |  5 |          1
(2 rows)
```

- Support specifying indexes when querying, only syntax support. `force index` enforces the use of the specified index; `ignore index` discards the specified index. see `SELECT`.

```
-- multiple index
select * from lt_test_mysql_ddl use
index(pk_lt_test_mysql_ddl,uk_lt_test_mysql_ddl);
select * from lt_test_mysql_ddl force
index(pk_lt_test_mysql_ddl,uk_lt_test_mysql_ddl);
```

```

select * from lt_test_mysql_ddl ignore
index(pk_lt_test_mysql_ddl,uk_lt_test_mysql_ddl);

-- multiple table join
select * from lt_test_mysql_ddl a use index for order
by(primary) join b using(id);
select * from lt_test_mysql_ddl a force index for order
by(pk_lt_test_mysql_ddl) join b using(id);
select * from lt_test_mysql_ddl a ignore index for order
by(primary,pk_lt_test_mysql_ddl) join b using(id);
select * from lt_test_mysql_ddl a ignore index for order
by(pk_lt_test_mysql_ddl) join b using(id);

```

- Support specifying engine, collate, character set, comment and other attributes when creating a table, among which engine and comment are only supported syntactically. Compatible with backquotes (") and tinyint type compatible. see Integer Types.
- Support duplicate key update syntax, when the PRIMARY KEY or UNIQU constraint is violated, update the operation, and vice versa. see ON DUPLICATE KEY UPDATE.

```

INSERT INTO t1 (a,b,c) VALUES (1,2,3) ON DUPLICATE KEY UPDATE
c=t1.c+1;

```

```

UPDATE t1 SET c=c+1 WHERE a=1;

```

- Support replace into syntax, when the PRIMARY KEY or UNIQU constraint is violated, delete the old tuple first, and then insert the new tuple. see REPLACE INTO.

```

lightdb@testdb=# REPLACE INTO test VALUES (1, 'Old name', '18');
INSERT 0 1

```

```

lightdb@testdb=# REPLACE INTO test VALUES (1, 'New name');
INSERT 0 1

```

```

lightdb@testdb=# SELECT * FROM test;
 id |          name          | age
-----+-----+-----
  1 | New name              |   0
(1 row)

```

### E.4.3.2. Oracle compatible

- Added no\_unnest and pq\_distribute optimization prompts. see lt\_hint\_plan.

no\_unnest optimization prompts.

```

lightdb@postgres=# EXPLAIN (COSTS false) select * from test1
where exists(select * from test2 where test1.key1=test2.key1);
QUERY PLAN

```

```

-----
Hash Join
Hash Cond: (test1.key1 = test2.key1)
-> Seq Scan on test1
-> Hash
    -> HashAggregate

```

```

Group Key: test2.key1
-> Seq Scan on test2
(7 rows)
lightdb@postgres=# EXPLAIN (COSTS false) select * from
test1 where exists(select/*+no_unnest*/ * from test2 where
test1.key1=test2.key1);
QUERY PLAN

```

```

-----
Seq Scan on test1 @"lt#1"
  Filter: (alternatives: SubPlan 1 or hashed SubPlan 2)
  SubPlan 1
    -> Seq Scan on test2 @"lt#0"
        Filter: (test1.key1 = key1)
  SubPlan 2
    -> Seq Scan on test2 test2_1 @"lt#0"
(7 rows)

```

pq\_distribute optimization prompts.

```

lightdb@lt_test=# /*+set(parallel_tuple_cost 0)
set(parallel_setup_cost 0) set(min_parallel_table_scan_size
0) set(min_parallel_index_scan_size 0)
set(max_parallel_workers_per_gather 8)*/
lightdb@lt_test=# EXPLAIN (COSTS false) SELECT /*+ leading(t1 t2)
hashjoin(t1 t2)*/ * FROM t1 join t2 on t1.id=t2.id;
QUERY PLAN

```

```

-----
Gather
  Workers Planned: 3
  -> Parallel Hash Join
      Hash Cond: (t1.id = t2.id)
      -> Parallel Seq Scan on t1 @"lt#0"
      -> Parallel Hash
          -> Parallel Seq Scan on t2 @"lt#0"
(7 rows)

```

```

lightdb@lt_test=# /*+set(parallel_tuple_cost 0)
set(parallel_setup_cost 0) set(min_parallel_table_scan_size
0) set(min_parallel_index_scan_size 0)
set(max_parallel_workers_per_gather 8)*/
lightdb@lt_test=# EXPLAIN (COSTS false) select/*+leading(t1 t2)
hashjoin(t1 t2) pq_distribute(t2 none broadcast)*/ * from t1
join t2 on t1.id=t2.id;
QUERY PLAN

```

```

-----
Gather
  Workers Planned: 3
  -> Hash Join
      Hash Cond: (t1.id = t2.id)
      -> Parallel Seq Scan on t1 @"lt#0"
      -> Hash
          -> Seq Scan on t2 @"lt#0"
(7 rows)

```

- Support Oracle to create user (CREATE USER)syntax; Supports cascading drop of users (DROP USER) and grant statements (see Examples).

for example:

```

CREATE USER user_name IDENTIFIED BY passwd DEFAULT TABLESPACE
dt_space TEMPORARY TABLESPACE tt_space;
DROP USER user_name CASCADE;
GRANT CONNECT TO HS_SES;
GRANT RESOURCE TO HS_SES;
GRANT UNLIMITED TABLESPACE TO HS_SES;

```

- Support global temporary tables. see Compatibility.
- Support Oracle global temporary session tables.
- Support Oracle global temporary transaction tables.

Create a session-level global temporary table.

```

CREATE GLOBAL TEMPORARY TABLE gtt_session(id number,ename
varchar(15)) ON COMMIT PRESERVE ROWS;

```

Create a transaction-level global temporary table.

```

CREATE GLOBAL TEMPORARY TABLE gtt_transaction(id number,ename
varchar(15)) ON COMMIT DELETE ROWS;

```

- Automatically create a user with the same name as the database, and the automatically created user with the same name has create, connect, temporary, login permissions in the created database, and this function cannot be used in distributed systems. see CREATE DATABASE.

```

lightdb@postgres=# create database testdb with
lightdb_syntax_compatible_type oracle;
NOTICE: auto create user "testdb" success
CREATE DATABASE

```

- When the length of the variable type declaration can be supported, it can be supported in characters or bytes, and when the unit is currently characters, only syntax is supported. see orafce.

```

create table hs_es(id int, name varchar2(10 byte));
create table hs_lt(id int, name varchar2(10 char));

```

- Added import tool ltldr, compatible with sqldr tool. By importing data from a specified table into the database through a control file, multiple tables can be imported at the same time. For businesses that use sqldr tools to import data, there are innate advantages.
- Compatible with DBMS\_UTILITY built-in package format\_error\_backtrace function, only record the latest record of the PlorasSQL execution error, use this function to view the location of the error. see support DBMS\_UTILITY built-in package format\_error\_backtrace.

Use function of DBMS\_UTILITY.format\_error\_backtrace, for example:

```

create or replace procedure pr_error_code_test1 is
v_backtrace varchar(1000);
v_error varchar(1000);

```

```

begin

    INSERT INTO test_error_stack values (2);
    INSERT INTO test_error_stack values (1);
    commit;
    exception when others then
        insert into t_errlog(operate_error_msg) select
to_char(DBMS_UTILITY.format_error_backtrace);
        commit;
        rollback;
    end pr_error_code_test1;
/

select select to_char(DBMS_UTILITY.format_error_backtrace)

```

- PloraSQL supports stored procedures to use both return parameters with out decoration and return returns as null. The return null function is to abort the stored procedure. see Returning from a Procedure.

```

create or replace procedure p_fmt_post_update_cash
(
    p_src_system varchar2 DEFAULT '0',
    p_init_date number DEFAULT 0,
    p_company_no varchar2 DEFAULT '0',
    o_return_msg out varchar2,
    o_return_code out integer
) as
    v_init_date int := 0;
begin
    if v_init_date = 0 then
        o_return_code := 1;
        o_return_msg := '#####';
    return;
    end if;
end;
/

```

## E.5. Release 13.8-22.4

**Release date:** 2022-12-27

- Add the guc parameter `lightdb_arch_mode`, and there are two values. `classic` means that the current data system is not a distributed architecture. `dist` means that the current data system is a distributed architecture, under this architecture, the table created with `create table` defaults to a distributed table. see Compatibility.
- `lt_check` is a LightDB check sha256sum tool. Ensure that the files in the LightDB installation directory are complete. see `lt_check`.
- Added detection for unconditional and pageless queries. see LightDB DML Specification Check.

In the following scenarios, a prompt message is printed indicating that the user should use pagination/where:

- `select` does not specify `limit`, `offset` or `where`.
- `update` does not specify `where`.

- delete does not specify where.

for example:

```
lightdb@lt_test=# set lightdb_best_practice_level to 'warn';
SET
lightdb@lt_test=# set lightdb_best_practice_mode to 'no_paging';
SET
lightdb@lt_test=# create table dc_np_t1(c_a int primary key,
    c_b varchar, gmt_create timestamp null, gmt_modified timestamp
    null);
CREATE TABLE
lightdb@lt_test=# SELECT * from dc_np_t1;
WARNING: LightDB DML check warning! select sql not where/limit/
offset clause!
  c_a | c_b | gmt_create | gmt_modified
-----+-----+-----+-----
(0 rows)
```

- Check the correctness of each item in the checklist. It can be used to detect whether there are risks in operating system parameters, LightDB installation file sha256sum, LightDB version number, etc. If there are risks, give a risk report. see `check_list`.
- Support `database()` functions can be used in both oracle and postgres modes. The `database()` function is placed in the extension `ltfce`. see `ltfce`.

for example:

```
lightdb@postgres=# select database();
database
-----
public
(1 row)
lightdb@postgres=# \c test_createdb_oracle
You are now connected to database "test_createdb_oracle" as user
"lightdb".
lightdb@test_createdb_oracle=# show
lightdb_dblevel_syntax_compatible_type;
lightdb_dblevel_syntax_compatible_type
-----
Oracle
(1 row)
lightdb@test_createdb_oracle=# select database();
database
-----
public
(1 row)
```

- Archive log cleaning optimization. see `lightdb_archive_dir`.
  - Remove the settings for the cleanup logic in `archive_command` from the installer script. Set `lightdb_archive_dir` at the same time.
  - When starting LightDB, check `archive_command`, `lightdb_archive_retion_size` and `lightdb_archive_dir` when `archive_mode` is on.
  - Adjustment parameters:

- `lightdb_archive_retion_size` can only be set at startup.
- `lightdb_archive_dir` can only be set at startup.
- Ensure that fewer wal logs are deleted in the archive than are retained in the `lt_wal` directory.
- Add `walminer` extension to mine all the useful information of wal logs to provide LightDB data recovery support. The database log level configuration needs to be greater than `minimal`. see `lt_walminer`.
- Supports single-instance multi-mode. see `CREATE DATABASE`.

for example:

```
lightdb@postgres=# create database test_createdb_oracle with
  lightdb_syntax_compatible_type oracle;
CREATE DATABASE
lightdb@postgres=# \c test_createdb_oracle
You are now connected to database "test_createdb_oracle" as user
  "lightdb".
lightdb@test_createdb_oracle=# show
  lightdb_dblevel_syntax_compatible_type;
  lightdb_dblevel_syntax_compatible_type
-----
Oracle
(1 row)
```

- Add the `lightdb_aborted_rollback` parameter to support the error reporting of the current statement in the transaction and rollback the entire transaction. see `lightdb_aborted_rollback`.

Before adding this feature,for example:

```
lightdb@lt_test=# begin;
BEGIN
lightdb@lt_test=# create table aborted_rollback(name
  varchar(100));
CREATE TABLE
lightdb@lt_test=# insert into aborted_rollback1 values(1);
ERROR:  relation "aborted_rollback1" does not exist
LINE 1: insert into aborted_rollback1 values(1);
          ^

lightdb@lt_test=!# insert into aborted_rollback1 values(1);
ERROR:  current transaction is aborted, commands ignored until
  end of transaction block
lightdb@lt_test=!# commit;
ROLLBACK
```

After adding this feature,for example:

```
lightdb@lt_test=# set lightdb_aborted_rollback to on;
SET
lightdb@lt_test=# begin;
BEGIN
lightdb@lt_test=# create table aborted_rollback(name
  varchar(100));
CREATE TABLE
```

```
lightdb@lt_test=*# insert into aborted_rollback1 values(1);
ERROR: relation "aborted_rollback1" does not exist
LINE 1: insert into aborted_rollback1 values(1);
          ^
ERROR: current transaction is aborted, "insert into
aborted_rollback1 values(1);" causes transaction rollback.
```

- Solve the problem of type mismatch when the unknown type participates in the operation. see optional.

for example:

```
lightdb@lt_test=# select '1'+1;
?column?
-----
          2
(1 row)
```

Note: Operator overloading may affect the return value of the expression. For example, for an expression such as `select '1' * 1`, it previously returned an int type, but now it returns a numeric type.

- The problem of high CPU usage in optimizing the `lt_cron` process. see `lt_cron`.
- Add an option `table_exists_action`, to tell `lt_restore` what to do if the table it is trying to create already exists. `table_exists_action` has four options: `skip`, `append`, `truncate` or `replace`. see `lt_restore`.
- `lt_upgrade` supports package upgrade. see `lt_upgrade`.
- `lt_upgradecheck` supports cross-version upgrade. see `lt_upgrade_check`.
- Statement level rollback optimization, This feature is supported in both Oracle and MySQL modes. Statement level rollback is enabled, and the performance loss is about 5%. see `lt_statement_rollback_enable`.
- `ltdts_ora` is a data synchronization tool for synchronizing Oracle data to LightDB. see `ltdts_ora`.
- `ltdts_mysql` is a data synchronization tool for synchronizing MySQL|MariaDB data to LightDB. see `ltdts_mysql`.
- `lt_patch` enhancements, and many of new parameters shown below have been added. see `lt_patch`.
  - Support automatic execution of SQL scripts.
  - Added `lt_patch` table to save patch information. The `apply_type` and `apply_version` attributes are added to the patch description information.
  - Add the patch dependency directory.
  - Solve the half state problem in the patch success process.
  - More stringent verification and other details optimization.
- Use `lt_dump` and `lt_restore` tools to implement backup and recovery of distributed clusters:
  - Use `lt_dump` tools to implement backup of distributed clusters. see `lt_distributed_dump`.
  - Use `lt_restore` tools to implement recovery of distributed clusters. see `lt_distributed_restore`.

- Use `lt_probackup` tools to implement backup and recovery of distributed clusters. see `lt_distributed_probackup`.
- Oracle compatibility enhancements, and many of new features shown below have been added.
- Online change from common table to partitioned table. see `ALTER TABLE`.

for example:

```
lightdb@test_createdb_oracle=# CREATE TABLE
  lt_oracle_partition_range5
lightdb@test_createdb_oracle=# (
lightdb@test_createdb_oracle(# a int,
lightdb@test_createdb_oracle(# b float,
lightdb@test_createdb_oracle(# c date,
lightdb@test_createdb_oracle(# d timestamp
lightdb@test_createdb_oracle(# )PARTITION BY RANGE (c)
lightdb@test_createdb_oracle=# (
lightdb@test_createdb_oracle(# PARTITION p1 VALUES LESS
  THAN(to_date('2022-01-01', 'yyyy-mm-dd')),
lightdb@test_createdb_oracle(#      PARTITION p2 VALUES LESS
  THAN(to_date('2022-02-01', 'yyyy-mm-dd')),
lightdb@test_createdb_oracle(#      PARTITION p3 VALUES LESS
  THAN(to_date('2022-03-01', 'yyyy-mm-dd'))
lightdb@test_createdb_oracle(# );
CREATE TABLE
lightdb@test_createdb_oracle=#
lightdb@test_createdb_oracle=# \d+ lt_oracle_partition_range5
          Partitioned table
"public.lt_oracle_partition_range5"
Column |          Type          | Collation | Nullable |
Default | Storage | Stats target | Description
-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
a      | integer          |           |          |
      | plain           |           |          |
b      | double precision |           |          |
      | plain           |           |          |
c      | date             |           |          |
      | plain           |           |          |
d      | timestamp without time zone |           |          |
      | plain           |           |          |
Partition key: RANGE (c)
Partitions: lt_oracle_partition_range5_1_prt_p1 FOR VALUES FROM
  (MINVALUE) TO ('2022-01-01'),
            lt_oracle_partition_range5_1_prt_p2 FOR VALUES FROM
  ('2022-01-01') TO ('2022-02-01'),
            lt_oracle_partition_range5_1_prt_p3 FOR VALUES FROM
  ('2022-02-01') TO ('2022-03-01')
```

- Support oracle cardinality and `ordered_predicates` hint. see `lt_hint_plan`.

for example:

```
lightdb@postgres=# explain select /*+ cardinality(b
  1000)use_nl(a b) leading(a b)*/* from t1 a , t2 b where
  a.key1=b.key1;
```

## QUERY PLAN

```
-----
Nested Loop (cost=0.15..433.43 rows=1000 width=16)
  -> Seq Scan on t1 a @"lt#0" (cost=0.00..32.60 rows=2260
width=8)
  -> Index Scan using t2_pkey on t2 b @"lt#0"
(cost=0.15..0.18 rows=1 width=8)
      Index Cond: (key1 = a.key1)
(4 rows)
```

```
lightdb@postgres=# EXPLAIN (COSTS false) select /*
+ordered_predicates*/ from test1 where mod(key1,10)=2 and
key2=2;
```

## QUERY PLAN

```
-----
Seq Scan on test1 @"lt#0"
  Filter: ((mod(key1, 10) = 2) AND (key2 = 2))
(2 rows)
```

- alter table modify, default values and not null attributes can swap locations. see ALTER TABLE.

for example:

```
lightdb@lt_test=# create table aborted_rollback(name
varchar(100));
CREATE TABLE
lightdb@lt_test=# alter table aborted_rollback modify name text
not null default 1;
ALTER TABLE
```

- New export tool ltuldr (compatible with oracle sqluldr2 tool). see ltuldr.
- Support connect by hierarchical query. see CONNECT BY Clause.

for example:

```
lightdb@test_createdb_oracle=# SELECT id, manager_id from t_tab
CONNECT BY prior id = manager_id order by id;
 id | manager_id
-----+-----
  1 |           0
  2 |           1
  2 |           1
  3 |           2
  3 |           2
  3 |           2
(6 rows)
```

- orafce Enhancements, see orafce.
- varchar2 calculates the length in characters.
- Support raw type.

for example:

```
lightdb@test_createdb_oracle=# create table test_type(name
varchar2(100), id raw);
```

```
CREATE TABLE
```

```
lightdb@test_createdb_oracle=# \d test_type
```

Column	Type	Collation	Nullable	Default
name	varchar2(100)			
id	raw			

## E.6. Release 13.8-22.3

LightDB 13.8-22.3 contains a variety of fixes and new feature from LightDB 13.3-22.2.

**Release date:** 2022-09-30

- Support q escape. for example:

```
select q'!name LIKE '%DBMS_%%'!';
       ?column?
```

```
-----
name LIKE '%DBMS_%%'
(1 row)
```

see Q-Quoted String Constants.

- Rownum performance optimization. Like oracle, support count stop key to improve rownum performance.

```
lightdb@lt_test=# explain select * from public.test where rownum
< 3;
```

```
QUERY PLAN
```

```
-----
Count StopKey (cost=0.00..0.03 rows=2 width=4)
-> Seq Scan on test (cost=0.00..159.75 rows=11475 width=4)
(2 rows)
```

- libpq supports getting LightDB version number.
- listagg supports for analytic functions. There is a description of listagg in the orafce chapter.
- NVL function parameters support more parameter combinations such as strings and numbers.
- Modify the default database to lt\_test, Replace the original default database postgres.
- lt\_upgrade supports upgrading LightDB from version 22.2 to version 22.3 (lt\_upgrade will check the consistency of lightdb\_syntax\_compatible\_type while upgrading, notice that if the value are both 'oracle', lt\_upgrade is not recommended). see lt\_upgrade.
- Add new GUC parameters nls\_date\_format and nls\_timestamp\_format for Oracle time function compatibility, see nls\_date\_format and nls\_timestamp\_format for more details.
- search\_path contains lt\_catalog by default. see Search Path.

schema oracle and mysql are processed specially, can only be set when they are consistent with the lightdb\_syntax\_compatible\_type.

- Support for non-reserved keywords as column aliases (When there is no keyword `as` and no quotation marks). see Key Words.

```
select 3 type;
      type
-----
      3
(1 row)
```

- when `lightdb_enable_default_tablespace` is enabled, add the default tablespace `lt_users`. The `lt_users` is the default tablespace of other databases created by ourselves. (unless overridden by a `TABLESPACE` clause in `CREATE DATABASE`). Its storage path is in the same level directory of the instance path. This can ensure that the amount of data under the instance path is not too large. see Tablespaces.
- `lightdb_service.py` supports any single node start stop.
- Fixed `lt_probackup` recovery failure for the amount of data exceeds 2G.
- Support for modifying column by `modify column clause` like oracle. see `ALTER TABLE` for details.
- Support the drop primary key clause when alter table. see `ALTER TABLE` for details.
- Add function and table for modifying tables that have view dependencies. see oracle for details.
- Remove read-only table related features.
- `lt_dump` enhancements, and many of new parameters shown below have been added. see `lt_dump`.
  - Add parameter `--lt-exclude-lightdb-objects` and parameter `--lt-dump-lightdb-tables`, To solve the problem of database object conflicts created by the LightDB built-in plug-in during export and import and to solve the problem of overwriting the table created by the LightDB built-in plug-in during import.
  - Add parameter `--lt-disable-auto-analyze`, To solve the problem of `lt_restore` multithreaded import deadlock.
- PL/oraSQL enhancements, and many of new features shown below have been added.
  - Package supports backup using `lt_dump`. see `lt_dump`.
  - Package supports associative arrays. see Section 42.8.
  - Support `table function`. see Table function.
  - Support `nested table`. see Nested Tables.
  - Support `error handling`. see Error Handling.
  - Support stored procedure(including stored procedure in `package`) and anonymous block after opening the cursor. in the transaction block, you can continue the fetch operation after `commit` or `rollback`. see `cursor-with-transactions`.
  - Fix open cursor parameter is inconsistent with the defined cursor parameter. see `cursor-default-values`.
- oracle Enhancements:

- Add new oracle's Built-in package: `dbms_metadata`, `dbms_job`, `dbms_lock`, `dbms_obfuscation_toolkit`, `utl_url`, `utl_encode`, `utl_raw` and `dbms_snapshot`.
- Improve the original built-in package: `dbms_application_info`, `dbms_utility` and `dbms_lob`.
- Add new oracle's system view like `[DBA/ALL/USER]_TABLES`, `[DBA/ALL/USER]_TAB_COLUMNS` and `[DBA/ALL/USER]_INDEXES`.
- Add new oracle's function: `BIN_TO_NUM`, `BITOR/BITXOR`, `REMAINDER`, `ROUND_TIES_TO_EVEN`, `INSTRB`, `REGEXP_INSTR/REGEXP_REPLACE`, `REPLACE`, `SOUNDEX`, `MONTHS_BETWEEN`, `TZ_OFFSET`, `CONVERT`, `NUMTOYMINTERVAL`, `TO_BLOB`, `NLS_CHARSET_ID /NLS_CHARSET_NAME`, `SYS_CONTEXT/USERENV`, `EMPTY_CLOB`, `ORA_HASH` and `VSIZE`.
- Add new oracle's agg function: `ANY_VALUE`, `BIT_AND_AGG/BIT_OR_AGG/ BIT_XOR_AGG`, `KURTOSIS_POP/KURTOSIS_SAMP` and `SKEWNESS_POP/ SKEWNESS_SAMP`.

see oracle for details.

- Oracle compatibility enhancements, and many of new features shown below have been added.
  - Support Oracle partition syntax. see `CREATE TABLE` and `ALTER TABLE`.
  - Support statement rollback. see `lt_statement_rollback_enable`.
  - Support `raise_application_error()` function. see Section 42.8.
  - `listagg` supports analysis functions. the oracle chapter.
  - Enhance compatibility between empty string and `NULL`. see Section 17.11.
- MySQL compatibility enhancements, and many of new features shown below have been added.
  - Support `year()` function.
  - Support `day()` function.
  - Support `date_format()` function.
  - Support `str_to_date()` function.
  - Support `from_unixtime()` function.
  - Support `unix_timestamp()` function.
  - Support `ifnull()` function.
  - Add interval constant compatibility.
  - Support `date_add()` function.
  - Support `date_sub()` function.
  - Support `dayofweek()` function.
  - Support `weekofyear()` function.

- Support `compress()` function.
- Support `uncompress()` function.
- Support `timestamp` and `string` comparison.
- Fix `smallint` error when using `'is true'` or `'= true'`.
- Fix `select` and `group by` field inconsistent report error.
- Fix `distinct` and `order by` field inconsistent report error.

see the `myfcs` chapter for details.

- JDBC driver library, We fixed some of the issues and enhanced data type compatibility:
  - Support `numeric` data type convert to Java Integer.
  - Add connection param `extendSchema`, The default value is `'lt_catalog,oracle'` when `currentSchema` is set, `extendSchema` will automatic append to `currentSchema`'s value.
  - Remove expiration time limit.
  - Support MySQL `SQL_CALC_FOUND_ROWS` and `SELECT FOUND_ROWS()` feature#only when they are executed sequentially.

## E.7. Release 13.3-22.2

**Release date:** 2022-06-30

- Support patch for quick upgrade, see `lt_patch`.
- Add `PL/oraSQL` loadable procedural language, see `plorasql`
- `lt_hint_plan` Enhancements
  - Add three new hints: `use_hash`, `use_nl`, `full`, semantics are consistent with Oracle.
  - The table name in hint is case-insensitive.
  - Hint `parallel` default is `hard` and supports no table specification.
  - Hints can be applied to the tables of the subquery when the subquery has only one table.

```
EXPLAIN (COSTS false) select /*+use_hash(t1 y)*/ from t1,
(select * from t2) y where t1.id=y.id;
```

QUERY PLAN

```
-----
Hash Join
Hash Cond: (t1.id = t2.id)
-> Seq Scan on t1 @"lt#0"
-> Hash
    -> Seq Scan on t2 @"lt#1"
(5 rows)
```

- Support User-defined type priority for better function and operator match, see type compatible.
- Support `CREATE TABLE DISTRIBUTED BY` to create distribute table(depends on extension canopy), see `CREATE TABLE`.

```
create table dist1(a int, b int) distributed by hash(a)
  shard_count(4);
```

- Auto-explain execution plan logs are printed in a separate log file (\*.slow) using JSON format.
- Add extension wal2sql to support Real-time synchronization to Oracle.
- `lt_dump` support `--recreate-schema` to generate drop schema(use CASCADE mode) command for better performance, see `lt_dump`.
- Client Applications and libpq Support LightDB environment variables.
- `sysdate` and `systimestamp` indicates the statement start time.

```
lightdb@postgres=# begin;
BEGIN
lightdb@postgres=# select sysdate from dual;
  sysdate
-----
2022-06-28 19:44:15
(1 row)

lightdb@postgres=# select sysdate from dual;
  sysdate
-----
2022-06-28 19:44:16
(1 row)

lightdb@postgres=# end;
COMMIT
```

For details, see `datetime`.

- When install with high availability, enable replication slot default.
- Support Order-Preserving Encryption ,see `lt_ope`
- The following platform support is added:

Architecture	OS
LoongArch <sup>1</sup>	Kylin V10(SP1) <sup>2</sup>
x86_64	rockylinux <sup>3</sup>
aarch64	rockylinux <sup>4</sup>

- Add cluster control tool `lightdb_service.py` to facilitate the overall start and stop of services in high availability and distributed environments.

start cluster:

```
lightdb_service.py -c start
```

<sup>1</sup> <https://www.loongson.cn/>

<sup>2</sup> <https://www.kylinos.cn/>

<sup>3</sup> <https://rockylinux.org/>

<sup>4</sup> <https://rockylinux.org/>

stop cluster:

```
lightdb_service.py -c stop
```

- The value 0 in PWR is display as empty, for details, see lt\_profile.
- In non-distributed installation, the canopy extension not installed.
- When keepalived and ltcluster are restarted, new log files are generated to avoid confusion with old logs.
- lt\_initdb does not restrict the order of options.
- Fix cannot assign XIDs during a parallel operation error occurs occasionally during parallel query in lt\_show\_plans.
- Release the JDBC driver library based on LightDB.
  - maven repository

```
<dependency>
  <groupId>io.github.hslightdb</groupId>
  <artifactId>lightdb-jdbc</artifactId>
  <version>42.2.30</version>
</dependency>
```

We fixed some of the issues and enhanced data type compatibility:

- fix#fetchSize does not take effect in automatic commit mode, causing the whole data to be loaded into the memory and causing out-of-memory problem.
- support oracle anonymous blocks syntax (see plorasql).
- support to\_number() function compatible with oracle.
- support numeric data type convert to Java Long.
- support char(1) data type convert to Java Character.
- fix loss of precision when Java setDouble operates on numeric field.
- lt\_cron supports linux command.

```
SELECT cron.schedule('daily-touch', '59 23 * * *', 'rm -rf
  $LTDATA/log/*', 'next', '8', 'linux');
```

- Built-in tool application lvs for load balancing in distributed environment wiith multi-CN.
- Built-in tool application postgresrest.
- Changed file naming rules in the installation directory and instance directory.
- The extension objects in public schema are all moved to the lt\_catalog schema.
- RPM dependencies are built into the installation package.
- Support merge into in distributed environment.

## E.8. Release 13.3-22.1

Release date: 2022-04-06

This release contains a variety of changes from LightDB 13.3-21.3.

- Oracle compatibility enhancements, and many of new features shown below have been added.
- If only one subquery is used in the `SELECT FROM` clause, you do not need to use the `as` clause to explicitly specify an alias for the subquery. See `SELECT` for more details.
- You can use `ROWNUM` as the filter condition in the `WHERE` clause of `UPDATE` and `DELETE` statements to specify the updated or deleted rows, for example:

```
UPDATE mytable SET column = value WHERE ROWNUM =  
rownum;  
DELETE FROM mytable WHERE ROWNUM = rownum;
```

You can also use `ROWNUM` to assign unique values to each row of a table, as in this example:

```
UPDATE mytable SET column = ROWNUM;
```

To use this feature, you need to set `lightdb_syntax_compatible_type` to `oracle`, for example:

```
SET lightdb_syntax_compatible_type = 'oracle';
```

See Section 7.9 for more details.

- Support `MERGE` syntax, `MERGE` performs actions that modify rows in the *target\_table\_name*, using the *data\_source*. `MERGE` provides a single SQL statement that can conditionally `INSERT` or `UPDATE` rows, a task that would otherwise require multiple procedural language statements. See `MERGE` for more details.
- support `SYSTIMESTAMP` function, `SYSTIMESTAMP` returns the system date, including fractional seconds and time zone, of the system on which the database resides. The return type is `TIMESTAMP WITH TIME ZONE`. For example:

```
SELECT SYSTIMESTAMP FROM DUAL;  
SELECT TO_CHAR(SYSTIMESTAMP, 'SSSS.FF') FROM DUAL;
```

See Section 9.9.4 for more details.

- If you have set `lightdb_syntax_compatible_type` to `oracle`, then the result of expression `"value || NULL"` will be the value, otherwise the result will be `NULL`.
- If you have set `lightdb_syntax_compatible_type` to `oracle`, then the result of expression `""::text is NULL"` will be true, otherwise the result will be false.
- The `LISTAGG` function in `orafce` extension now support `DISTINCT` and `WITHIN GROUP` syntax, you can use it as in this example:

```
SELECT LISTAGG(DISTINCT column, ',') WITHIN GROUP  
(ORDER BY column) FROM mytable;
```

- Add new keyword MINUS for SELECT statements and as the alias of EXCEPT, they are completely equivalent. See SELECT for more details.
- GUC parameters `lightdb_enable_rowid` and `lightdb_enable_rownum` are removed, and set `lightdb_syntax_compatible_type` to `oracle` to instead.
- `pg_hint_plan` enhancements and several new hints such as `USE_HASH_AGGREGATION`, `Semijoin`, `Antijoin` and `Swap_join_inputs` have been added. Besides, it also realizes the support of canopy for distributed database. See `lthint_plan` for more details.
- Support Transparent Data Encryption(TDE). TDE can (and can only) be enabled by specifying the `-K` option when generating a data directory using `initdb` or `lt_initdb`, and this option passes in a 32-bytes hexadecimal key string, which is used for encryption and decryption. See encryption key command for more details.
- Adding new extension `lt_sm` to support `sm2`, `sm3` and `sm4` encryption. `lt_sm` is a extension for LightDB that provides a series of functions for `sm2`, `sm3` and `sm4` encryption algorithms. Data can be encrypted and decrypted using the above functions. See `lt_sm` for more details.
- Adding New GUC parameters `lightdb_tsearch_non_stopwords` and `lightdb_tsearch_word_superpose` for full text search.

LightDB full text search has many built-in stop words. Words connected by stop words will be split into multiple independent words by `to_tsvector` function, for example, "2022-04-10" will be split into "2022", "04" and "10".

`lightdb_tsearch_non_stopwords` is used to customize non-stop words, which is just the opposite of stop words, that is, non-stop words are considered to be an integral part of a word and thus will not be split into multiple independent words by `to_tsvector` function any more. Still the above example, if you set '-' as non-stop words, you will only get a result of "2022-04-10".

`lightdb_tsearch_word_superpose` is used to overlay the effect of using stop words and non-stop words. For example, if you set `lightdb_tsearch_word_superpose` to `on` and set `lightdb_tsearch_non_stopwords` to '-', you will get the results including "2022", "04", "10" and "2022-04-10" at the same time when using `to_tsvector("2022-04-10")`.

See Section 12.1.3 for more details.

- Adding new GUC parameters `lt_ring_buffers` to set the maximum amount of memory used for ring buffers within each database session. When running a sequential scan query that needs to access a large number of pages(more than a quarter of the total pages of `shared_buffers`) just once, a special access strategy called bulk-read is used. A page that has been touched only by such a scan is unlikely to be needed again soon, so instead of blowing out the entire buffer cache, a small ring of buffers that specified by `lt_ring_buffers` is allocated and those buffers are reused for the whole scan. This also implies that much of the write traffic caused by such a statement will be done by the backend itself and not pushed off onto other processes.
- `pg_profile` enhancements, adding new `wait_event_type` named `DBCpu` in wait event statistics, which indicate how much cpu time the user activity spends on database. See `pgprofile` for more details.
- `pg_cron` enhancements, support three task scheduling modes: `asap`, `next interval` and `fixed interval`.
  - `asap`: Each task creates only one session and corresponds to a task queue, and multiple tasks can be stored in the queue. If the subsequent scheduling cycle comes during the execution of the current task, they will be put into the queue. At the same time, the current execution will complete all tasks in the queue one by one.
  - `next interval`: Each task creates only one session and corresponds to a task queue, and only one task is stored in the queue. If the subsequent scheduling cycle comes during the execution of

the current task, they will not be put into the queue, but the next scheduling cycle after current task execution.

- fixed interval: This mode is similar to next interval, but the difference is that if the subsequent scheduling cycle comes during the execution of the current task, a separate session will be created for the subsequent scheduling to execute, that is, multiple scheduling tasks will be executed in parallel, but the maximum number of parallel executions is `cron.max_connections_per_task`.

In addition, the task timeout function is also added. If the task execution time exceeds the specified maximum time, the task will be forcibly interrupted and `cron.job_run_details` will record relevant error messages. The default timeout is 15s, which is determined by `cron.task_running_timeout`. This parameter can only take effect when the database is started.

See `lt_cron` for more details.

- Adding new GUC parameters `pg_prewarm.lt_autoprewarm_dbs`, `pg_prewarm.lt_autoprewarm_tables` and `pg_prewarm.lt_autoprewarm_indexes` for `pg_prewarm` extension, which are used to selectively prewarm the specified database, table and index automatically when LightDB is started. See `lt_prewarm` for more details.
- Canopy extension is enabled by default now.
- New extension `pg_show_plans` is integrated and disabled by default. See `lt_show_plans` for more details.
- Automatically ANALYZE when execute CREATE INDEX to collect statistics.
- UPDATE and DELETE statement allow use LIMIT clause to limit the rows will be updated and deleted, for example:

```
UPDATE mytable SET column = value LIMIT n;
DELETE FROM mytable WHERE column > value LIMIT m, n;
```

See UPDATE and DELETE for more details.

- If you use function(include built-in function and user defined function) to specify the default value of a column in CREATE TABLE statement, the function parameters can be other column names, variable names, and expressions containing other column names and variable names, for example:

```
CREATE FUNCTION myfunc(v integer)
RETURNS integer AS $$
BEGIN
    RETURN v + 10;
END;
$$ LANGUAGE plpgsql;

CREATE TABLE mytable (
    id    int    default 10,
    key   int    default myfunc(id),
    v1    int    default key,
    v2    int    default key + myfunc(key)
);
```

See CREATE TABLE for more details.

- When using "CREATE TABLE AS SELECT colname AS alias" to create a table, ltapk is not allowed as the alias. See CREATE TABLE for more details.
- `lt_standby_forward` (EXPERIMENTAL) is a module which forwards SQL statements from a hot standby to primary, providing a facility to reduce loading of primary and allow clients query from standby. For example, client can send INSERT, CREATE to a hot standby. See `lt_standby_forward` for more details.
- The sqlprompt format of ltsql is adjusted to `username@database`.

## E.9. Release 13.3-21.3

**Release date:** 2021-12-31

This release contains a variety of changes from LightDB 13.3-21.2.

- WAL (Write-Ahead Log) can be placed on Intel Optane PMEM, achieving significant improvements in recovery time and performance. To enable this feature, set GUC option `wal_sync_method` to `pmem_drain`. See `wal_sync_method` for details.
- MySQL compatibility enhancements
  - functions support: `find_in_set()`, `group_concat()`, `if()`, `truncate()`, `datediff()`, `locate()` and `database()`. See `myfce` for details.
  - longtext data type support
  - LIMIT(m, n) syntax support. See Section 7.6 for details.
- Oracle compatibility enhancements, including data type implicit conversion between number (such as `int2`, `int4`, `int8`, `float4`, `float8` and `numeric`) and string (such as `char`, `varchar`, `text` and `unknow`). See Chapter 10 for details.
- Autovacuum when setting a table read only. No more manual execution.
- Wildcards '%' can be used when viewing GUC parameters with SHOW statement. For example, you can use it like "SHOW max%", "SHOW %timeout" and "SHOW %vacuum%". See SHOW for details.
- Alias can be used when updating a single table with UPDATE statement. For example, you can use it like "UPDATE mytable AS t SET t.colname = value WHERE t.id = 1".
- Support automatic cleaning of archived WAL and log files according to specified rules. See Section 17.5.3 for details.
  - Archived WAL: clean up archived wal files in archive dir (`lightdb_archive_dir`) older than (`checkpoint file - lightdb_archive_retention_size`) when archive wal success. For example: `lightdb_archive_retention_size = 2`. checkpoint file is `000000010000000000000008`, will remove the file older than `000000010000000000000006`.
  - log files: by setting `lightdb_log_retention_age` to N Mins (usually set to `xxx` to remove file `xxx` days ago) to remove files older than N Mins. Execute when switching to a new file. The time depends on file modification time.
- COPY and `pg_bulkload` support multi character separators (at most three) for text. See COPY for details.

```
COPY country TO STDOUT (DELIMITER 'ABC');
```

- Modify default search\_path to contains oracle schema. This means functions and data types in orafce extension can be used anywhere directly.
- integrate Citus extension, but not enabled by default.
- integrate pg\_pathman extension and enabled by default.
- Enhance pg\_profile, adding database time statistics in LightDB profile report(PWR). See pgprofile for details.
- Enhance pg\_hint\_plan, including multi hint support, hint scope qualification, qb\_name syntax support and no\_merge hint syntax support. Now you can use hint only for sub query. See lthint\_plan for details.
- Enhance pg\_cron, including second level timed task support and one time scheduled task support. In addition, the default time zone of the task is adjusted to UTC/GMT+08:00. See lt\_cron for details.
- Enhance system\_stats, adding a new function lt\_get\_sys\_kernel\_settings() to get linux kernel parameters.
- lt\_initdb command line parameters support specifying non default port number(-p). For example: lt\_initdb -p xxx -D xxx. See lt\_initdb for details.
- Support ROWNUM. ROWNUM is a pseudocolumn like oracle ROWNUM. Each row returns by a query, the ROWNUM pseudocolumn returns a number indicating the order in which LightDB selects the row from a table or a set of joined rows.

Now ROWNUM supports using with order by, group by, subquery, join, union and partition table. However, it is not supported in update or deletion, and it is not supported in column expression(like selecting rownum + 1 from xxx ). See Section 7.9 for details.

- The following extensions is removed from LightDB.
  - pg\_wait\_sampling
  - timescaledb

## E.10. Release 13.3-21.2

**Release date:** 2021-10-24

This release contains a variety of changes from LightDB 13.3-21.1.

- This version contains a database monitor and management platform, the LightDB Enterprise Manager (LightDB-EM) embedded version, provides monitoring and management solution for LightDB.
- New Installation Wizard, with GUI and CLI mode. Allows you to simply and easily install standalone or high-available deployment LightDB, including the LightDB-EM.
- Enhance PWR and ASH, especially wait-event. Helping you to find out most resource-consuming activities and top SQL in your LightDB databases.
- Enhance Oracle compatilby, as following: Function. rowid, sysdate, nvl function supports numeric, real, integer, text, varchar, bpchar, bit conversion. guid function. DataTypee. clob, blob, varchar2, number, rowid.
- Enhance MySQL compatilby, as following: Function. uuid function. DataTypee. datetime. Syntax and features. Supporting AUTO\_INCREMENT, ON UPDATE CURRENT\_TIMESTAMP.

- Add a new GUC parameter `lightdb_keep_temp_file`, for debug purpose. Allowing temporary files, such as sort and hash temporary files, be retained.
- Add Ordered optimizer hint, which is equivalent to Leading optimizer hint.
- To Improve database design and best practice, LightDB introduce design checking through DDL. Five kinds of checkings are supporting now: `keyword_not_allowed`, `bad_datatype`, `must_have_pk`, `must_have_gmt`, `no_more_100cols`. these rules can enable all or enable as needed, like MySQL's `sql-mode`. GUC parameters `lightdb_best_practice_mode` and `lightdb_best_practice_level` used for controlling the rule. Existing object all not affected.
- To improve legacy system pull-mode incremental-sync speed, LightDB support hidden auto-increment primary key column and hidden update timestamp column. Add `WITH PRIMARY KEY` to create an implicit column `ltapk`, which will be incremented automatically when a new row is inserted. Add `WITH UPDATE CURRENT_TIMESTAMP` to create an implicit column `ltau`, which will be updated automatically when row a is inserted or modified.
- The following built-in extensions are auto enabled by default in every database, user don't need to perform `CREATE EXTENSION` manually.
  - `pg_log_long_xact`, `pl/pgsql` function to log long running transactions
  - `pg_bulkload`, `pg_bulkload` is a high speed data loading utility for LightDB, an replacement for `COPY` command
  - `system_stats`, system statistic functions for LightDB
  - `timescaledb`, enables scalable inserts and complex queries for time-series data
  - `zhparser`, a parser for full-text search of Chinese. The default configuration name is `zhcfg`
  - `rum`, RUM index access method, a faster full text search implementation.
  - `tsvector2`, a extended format of `tsvector`, a better space usage datatype for full text search.
- The following extensions are also built-in but not enabled by default, perform `CREATE EXTENSION` before using them.
  - `mysql_fdw`, a Foreign Data Wrapper (FDW) for MySQL
  - `oracle_fdw`, a Foreign Data Wrapper for Oracle

## E.11. Release 13.3-21.1

**Release date:** 2021-08-17

This is the first GA release of LightDB.

- The default values of some GUC parameters have been modified for better performance for modern hardware.
- The native partition can be declared in clause statement of `CREATE TABLE`, which supports list, range and hash syntax.
- Add `lightdb_explain_no_runtime_pruned_partition` parameter to control whether partitions pruned at runtime are shown in `EXPLAIN ANALYZE` output.
- Built-in `pg_hint_plan`, which can control the execution plan with hinting phrases in comment of special form.

- Built-in `pg_wait_sampling`, which provides sampling based statistics of wait events.
- Built-in `pg_profile`, which can help you to find out most resource-consuming activities in your LightDB databases.
- Built-in `pg_cron`, a simple cron-based job scheduler that runs inside the database. It uses the same syntax as regular cron, but it allows you to schedule LightDB commands directly from the database.
- Built-in `pg_cheat_funcs`, which provides a set of cheat(but useful) functions on LightDB.
- Built-in `pgfincore`, which provides a set of functions to handle low-level management of relations using mincore to explore cache memory.
- Built-in `orafce`, an Oracle's compatibility functions and packages.
- Built-in `pgaudit`, which provides detailed session and/or object audit logging via the standard LightDB logging facility.
- Built-in `pg_probackup`, which manages backup and recovery of LightDB database clusters.
- The following built-in extensions are auto enabled by default in every database(Except `dblink`, `pg_profile` and `pg_cron`, which is only available in postgres database), you don't need to perform `CREATE EXTENSION` manually.
  - `pg_stat_statements`
  - `auto_explain`
  - `tablefunc`
  - `dblink`
  - `uuid-oss`
  - `pg_hint_plan`
  - `pg_wait_sampling`
  - `pg_profile`
  - `pg_cron`
  - `pgfincore`
  - `orafce`
  - `pgaudit`

Specially, a `pg_cron` job named "take\_sample\_every\_10min" will be created automatically by default in postgres database. This job will call `take_sample()` every 10 minutes (`take_sample()` is provided by `pg_profile` extension).

---

# Appendix F. Additional Supplied Modules

This appendix and the next one contain information regarding the modules that can be found in the `contrib` directory of the LightDB distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core LightDB system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers extensions and other server plug-in modules found in `contrib`. Appendix G covers utility programs.

If you are using a pre-packaged version of LightDB, these modules are typically made available as a separate subpackage, such as `lightdb-contrib`.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a `CREATE EXTENSION` command. In a fresh database, you can simply do

```
CREATE EXTENSION module_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in each database that you want the module's facilities to be available in. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

For all these modules, `CREATE EXTENSION` must be run by a database superuser, unless the module is considered “trusted”, in which case it can be run by any user who has `CREATE` privilege on the current database. Modules that are trusted are identified as such in the sections that follow. Generally, trusted modules are ones that cannot provide access to outside-the-database functionality.

Many modules allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these modules are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of `shared_preload_libraries`. See the documentation of each module for details.

## F.1. adminpack

`adminpack` provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is only allowed to the superuser by default but may be allowed to other users by using the `GRANT` command.

The functions shown in Table F.1 provide write access to files on the machine hosting the server. (See also the functions in Table 9.96, which provide read-only access.) Only files within the database cluster directory can be accessed, unless the user is a superuser or given one of the `pg_read_server_files`, or `pg_write_server_files` roles, as appropriate for the function, but either a relative or absolute path is allowable.

**Table F.1. adminpack Functions**

Function	Description
<code>pg_catalog.pg_file_write ( filename text, data text, append boolean ) → bigint</code>	Writes, or appends to, a text file.
<code>pg_catalog.pg_file_sync ( filename text ) → void</code>	Flushes a file or directory to disk.
<code>pg_catalog.pg_file_rename ( oldname text, newname text [, archivename text ] ) → boolean</code>	Renames a file.
<code>pg_catalog.pg_file_unlink ( filename text ) → boolean</code>	Removes a file.
<code>pg_catalog.pg_logdir_ls () → setof record</code>	Lists the log files in the <code>log_directory</code> directory.

`pg_file_write` writes the specified *data* into the file named by *filename*. If *append* is false, the file must not already exist. If *append* is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

`pg_file_sync` fsyncs the specified file or directory named by *filename*. An error is thrown on failure (e.g., the specified file is not present). Note that `data_sync_retry` has no effect on this function, and therefore a PANIC-level error will not be raised even on failure to flush database files.

`pg_file_rename` renames a file. If *archivename* is omitted or NULL, it simply renames *oldname* to *newname* (which must not already exist). If *archivename* is provided, it first renames *newname* to *archivename* (which must not already exist), and then renames *oldname* to *newname*. In event of failure of the second rename step, it will try to rename *archivename* back to *newname* before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

`pg_file_unlink` removes the specified file. Returns true on success, false if the specified file is not present or the `unlink()` call fails; other cases throw errors.

`pg_logdir_ls` returns the start timestamps and path names of all the log files in the `log_directory` directory. The `log_filename` parameter must have its default setting (`lightdb-%Y-%m-%d_%H%M%S.log`) to use this function.

## F.2. amcheck

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations. If the structure appears to be valid, no error is raised.

The functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect

binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See Section 36.16.3 for details of operator class support functions.

amcheck functions may only be used by superusers.

## F.2.1. Functions

`bt_index_check(index regclass, heapallindexed boolean)` returns void

`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```
test=# SELECT bt_index_check(index => c.oid, heapallindexed =>
      i.indisunique),
      c.relname,
      c.relpages
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;
```

bt_index_check	relname	relpages
	pg_depend_reference_index	43
	pg_depend_depender_index	40
	pg_proc_proname_args_nsp_index	31
	pg_description_o_c_o_index	21
	pg_attribute_relid_attnam_index	14
	pg_proc_oid_index	10
	pg_attribute_relid_attnum_index	9
	pg_amproc_fam_proc_index	5
	pg_amop_opr_fam_index	5
	pg_amop_fam_strat_index	5

(10 rows)

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when `heapallindexed` is `true`. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

```
bt_index_parent_check(index regclass, heapallindexed boolean,
rootdescend boolean) returns void
```

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the *heapallindexed* argument is `true`, the function verifies the presence of all heap tuples that should be found within the index. When the optional *rootdescend* argument is `true`, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when Hot Standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

### Tip

`bt_index_check` and `bt_index_parent_check` both output log messages about the verification process at `DEBUG1` and `DEBUG2` severity levels. These messages provide detailed information about the verification process that may be of interest to LightDB developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive `lsql` session before running a verification query will display messages about the progress of verification with a manageable level of detail.

## F.2.2. Optional *heapallindexed* Verification

When the *heapallindexed* argument to verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

### F.2.3. Using `amcheck` Effectively

`amcheck` can be effective at detecting various types of failure modes that data page checksums will always fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a master server and a standby server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See Section 21.1 and Section 21.2 for further details about how LightDB uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying LightDB access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed LightDB features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests. See Section 30.1 for details on running the tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

LightDB does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

When *heapallindexed* verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

## F.2.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. `pageinspect` may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

## F.3. `auth_delay`

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via `shared_preload_libraries` in `lightdb.conf`.

### F.3.1. Configuration Parameters

`auth_delay.milliseconds` (int)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `lightdb.conf`. Typical usage might be:

```
# lightdb.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

### F.3.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

## F.4. `auto_explain`

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in

`lightdb.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

The `auto_explain` module will also generate a separate log file which called slow log. A slow log file has the same basename as the default log file and a ".slow" suffix. The format of slow log is always json.

## F.4.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration` (integer)

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_analyze` (boolean)

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

### Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers` (boolean)

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_wal` (boolean)

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the `WAL` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing` (boolean)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers` (boolean)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_settings` (boolean)

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_level` (enum)

`auto_explain.log_level` selects the log level at which `auto_explain` will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (real)

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `lightdb.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# lightdb.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

## F.4.2. Example

```
lightdb@postgres=# LOAD 'auto_explain';
lightdb@postgres=# SET auto_explain.log_min_duration = 0;
lightdb@postgres=# SET auto_explain.log_analyze = true;
lightdb@postgres=# SELECT count(*)
```

```
FROM pg_class, pg_index
WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG: duration: 3.651 ms plan:
Query Text: SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
Aggregate (cost=16.79..16.80 rows=1 width=0) (actual
time=3.626..3.627 rows=1 loops=1)
  -> Hash Join (cost=4.17..16.55 rows=92 width=0) (actual
time=3.349..3.594 rows=92 loops=1)
    Hash Cond: (pg_class.oid = pg_index.indrelid)
    -> Seq Scan on pg_class (cost=0.00..9.55 rows=255
width=4) (actual time=0.016..0.140 rows=255 loops=1)
    -> Hash (cost=3.02..3.02 rows=92 width=4) (actual
time=3.238..3.238 rows=92 loops=1)
      Buckets: 1024 Batches: 1 Memory Usage: 4kB
      -> Seq Scan on pg_index (cost=0.00..3.02 rows=92
width=4) (actual time=0.008..3.187 rows=92 loops=1)
    Filter: indisunique
```

## F.4.3. Author

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>

## F.5. bloom

`bloom` provides an index access method based on Bloom filters<sup>1</sup>.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

### F.5.1. Parameters

A bloom index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

---

<sup>1</sup> [https://en.wikipedia.org/wiki/Bloom\\_filter](https://en.wikipedia.org/wiki/Bloom_filter)

col1 - col32

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

## F.5.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
    WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes i1 and i2 mapped to 2 bits, and attribute i3 mapped to 4 bits. We could have omitted the length, col1, and col2 specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
    SELECT
        (random() * 1000000)::int as i1,
        (random() * 1000000)::int as i2,
        (random() * 1000000)::int as i3,
        (random() * 1000000)::int as i4,
        (random() * 1000000)::int as i5,
        (random() * 1000000)::int as i6
    FROM
        generate_series(1,10000000);
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 =
    123451;
```

QUERY PLAN

```
-----
Seq Scan on tbloom (cost=0.00..2137.14 rows=3 width=24) (actual
time=15.480..15.480 rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning Time: 0.340 ms
Execution Time: 15.501 ms
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
```

```
-----
3976 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 =
123451;
```

QUERY PLAN

```
-----
Seq Scan on tbloom (cost=0.00..2137.00 rows=2 width=24) (actual
time=12.604..12.604 rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning Time: 0.155 ms
Execution Time: 12.617 ms
(5 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5,
i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
```

```
-----
1584 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 =
123451;
```

QUERY PLAN

```
-----
Bitmap Heap Scan on tbloom (cost=1792.00..1799.69 rows=2
width=24) (actual time=0.384..0.384 rows=0 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 26
  Heap Blocks: exact=26
  -> Bitmap Index Scan on bloomidx (cost=0.00..1792.00 rows=2
width=0) (actual time=0.350..0.350 rows=26 loops=1)
    Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning Time: 0.122 ms
Execution Time: 0.407 ms
(8 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
```

```

=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 =
  123451;

```

QUERY PLAN

```

-----
Bitmap Heap Scan on tbloom (cost=24.34..32.03 rows=2 width=24)
(actual time=0.032..0.033 rows=0 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
    -> BitmapAnd (cost=24.34..24.34 rows=2 width=0) (actual
time=0.029..0.030 rows=0 loops=1)
      -> Bitmap Index Scan on btreeidx5 (cost=0.00..12.04
rows=500 width=0) (actual time=0.029..0.029 rows=0 loops=1)
        Index Cond: (i5 = 123451)
      -> Bitmap Index Scan on btreeidx2 (cost=0.00..12.04
rows=500 width=0) (never executed)
        Index Cond: (i2 = 898732)
Planning Time: 0.537 ms
Execution Time: 0.064 ms
(9 rows)

```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 2 MB, so the total space needed is 12 MB, eight times the space used by the bloom index.

### F.5.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```

CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
  OPERATOR      1      =(text, text),
  FUNCTION      1      hashtext(text);

```

### F.5.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- bloom access method doesn't support `UNIQUE` indexes.
- bloom access method doesn't support searching for `NULL` values.

### F.5.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Hundsun Technologies Inc, Hangzhou, China

Alexander Korotkov <a.korotkov@postgrespro.ru>, Hundsun Technologies Inc, Hangzhou, China

Oleg Bartunov <obartunov@postgrespro.ru>, Hundsun Technologies Inc, Hangzhou, China

## F.6. btree\_gin

`btree_gin` provides sample GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `"char"`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `name`, `bool`, `bpchar`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

### F.6.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

### F.6.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin> for additional information.

## F.7. btree\_gist

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` (“not equals”). This may be useful in combination with an exclusion constraint, as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with`

time zone, timestamp without time zone, time without time zone, date, interval, oid, and money.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

## F.7.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
    cage    INTEGER,
    animal  TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint
        "zoo_cage_animal_excl"
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key
        (cage, animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```

## F.7.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<jankorichter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See <http://www.sai.msu.su/~megeera/postgres/gist/> for additional information.

## F.8. canopy

See `canopy`<sup>2</sup> for more details.

## F.9. citext

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

---

<sup>2</sup> <http://www.light-pg.com/docs/canopy/13.8-23.4/index.html>

**Tip**

Consider using *nondeterministic collations* (see Section 21.2.2.4) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

## F.9.1. Rationale

The standard approach to doing case-insensitive matches in LightDB has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

## F.9.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT NOT NULL  
);  
  
INSERT INTO users VALUES ( 'larry',  
    sha256(random)::text::bytea );  
INSERT INTO users VALUES ( 'Tom',  
    sha256(random)::text::bytea );  
INSERT INTO users VALUES ( 'Damian',  
    sha256(random)::text::bytea );  
INSERT INTO users VALUES ( 'NEAL',  
    sha256(random)::text::bytea );  
INSERT INTO users VALUES ( 'Bjørn',  
    sha256(random)::text::bytea );
```

```
SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

### F.9.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the `regexp` functions, if you want to match case-sensitively, you can specify the “`c`” flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

### F.9.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- As of LightDB 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.
- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only

`text` can support B-Tree deduplication. However, `citext` is slightly more efficient than using `lower` to get case-insensitive matching.

- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.
- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode distinguishes between *case mapping* and *case folding* for this reason. Use nondeterministic collations instead of `citext` to handle that correctly.

## F.9.5. Author

David E. Wheeler <david@kineticcode.com>

Inspired by the original `citext` module by Donald Fraser.

## F.10. cube

This module implements a data type `cube` for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.10.1. Syntax

Table F.2 shows the valid external representations for the `cube` type. `x`, `y`, etc. denote floating-point numbers.

**Table F.2. Cube External Representations**

External Syntax	Meaning
<code>x</code>	A one-dimensional point (or, zero-length one-dimensional interval)
<code>(x)</code>	Same as above
<code>x1, x2, . . . , xn</code>	A point in n-dimensional space, represented internally as a zero-volume cube
<code>(x1, x2, . . . , xn)</code>	Same as above
<code>(x), (y)</code>	A one-dimensional interval starting at <code>x</code> and ending at <code>y</code> or vice versa; the order does not matter
<code>[(x), (y)]</code>	Same as above
<code>(x1, . . . , xn), (y1, . . . , yn)</code>	An n-dimensional cube represented by a pair of its diagonally opposite corners
<code>[(x1, . . . , xn), (y1, . . . , yn)]</code>	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so `[ ( x ) , ( y ) ]` is the same as `[ ( x ) , ( y ) ]`.

## F.10.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

## F.10.3. Usage

Table F.3 shows the specialized operators provided for type `cube`.

**Table F.3. Cube Operators**

Operator	Description
<code>cube &amp;&amp; cube</code>	<code>→ boolean</code> Do the cubes overlap?
<code>cube @&gt; cube</code>	<code>→ boolean</code> Does the first cube contain the second?
<code>cube &lt;@ cube</code>	<code>→ boolean</code> Is the first cube contained in the second?
<code>cube -&gt; integer</code>	<code>→ float8</code> Extracts the $n$ -th coordinate of the cube (counting from 1).
<code>cube ~&gt; integer</code>	<code>→ float8</code> Extracts the $n$ -th coordinate of the cube, counting in the following way: $n = 2 * k - 1$ means lower bound of $k$ -th dimension, $n = 2 * k$ means upper bound of $k$ -th dimension. Negative $n$ denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.
<code>cube &lt;-&gt; cube</code>	<code>→ float8</code> Computes the Euclidean distance between the two cubes.
<code>cube &lt;#&gt; cube</code>	<code>→ float8</code> Computes the taxicab (L-1 metric) distance between the two cubes.
<code>cube &lt;=&gt; cube</code>	<code>→ float8</code> Computes the Chebyshev (L-inf metric) distance between the two cubes.

(Before LightDB 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a `UNIQUE` constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a cube GiST index can be used to find nearest neighbors using the metric operators <->, <#>, and <=> in ORDER BY clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The ~> operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F.4 shows the available functions.

**Table F.4. Cube Functions**

Function	Description	Example(s)
<code>cube ( float8 )</code>	→ cube Makes a one dimensional cube with both coordinates the same.	<code>cube(1) → (1)</code>
<code>cube ( float8, float8 )</code>	→ cube Makes a one dimensional cube.	<code>cube(1,2) → (1), (2)</code>
<code>cube ( float8[] )</code>	→ cube Makes a zero-volume cube using the coordinates defined by the array.	<code>cube(ARRAY[1,2,3]) → (1, 2, 3)</code>
<code>cube ( float8[], float8[] )</code>	→ cube Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.	<code>cube(ARRAY[1,2], ARRAY[3,4]) → (1, 2), (3, 4)</code>
<code>cube ( cube, float8 )</code>	→ cube Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.	<code>cube('(1,2),(3,4)::cube, 5) → (1, 2, 5), (3, 4, 5)</code>
<code>cube ( cube, float8, float8 )</code>	→ cube Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.	<code>cube('(1,2),(3,4)::cube, 5, 6) → (1, 2, 5), (3, 4, 6)</code>
<code>cube_dim ( cube )</code>	→ integer Returns the number of dimensions of the cube.	<code>cube_dim('(1,2),(3,4)') → 2</code>

Function	Description	Example(s)
<code>cube_ll_coord</code>	<code>cube_ll_coord ( cube, integer ) → float8</code> Returns the <i>n</i> -th coordinate value for the lower left corner of the cube.	<code>cube_ll_coord( '(1,2),(3,4)', 2) → 2</code>
<code>cube_ur_coord</code>	<code>cube_ur_coord ( cube, integer ) → float8</code> Returns the <i>n</i> -th coordinate value for the upper right corner of the cube.	<code>cube_ur_coord( '(1,2),(3,4)', 2) → 4</code>
<code>cube_is_point</code>	<code>cube_is_point ( cube ) → boolean</code> Returns true if the cube is a point, that is, the two defining corners are the same.	<code>cube_is_point(cube(1,1)) → t</code>
<code>cube_distance</code>	<code>cube_distance ( cube, cube ) → float8</code> Returns the distance between two cubes. If both cubes are points, this is the normal distance function.	<code>cube_distance( '(1,2)', '(3,4)' ) → 2.8284271247461903</code>
<code>cube_subset</code>	<code>cube_subset ( cube, integer[] ) → cube</code> Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.	<code>cube_subset(cube( '(1,3,5),(6,7,8)' ), ARRAY[2]) → (3),(7)</code> <code>cube_subset(cube( '(1,3,5),(6,7,8)' ), ARRAY[3,2,1,1]) → (5, 3, 1, 1),(8, 7, 6, 6)</code>
<code>cube_union</code>	<code>cube_union ( cube, cube ) → cube</code> Produces the union of two cubes.	<code>cube_union( '(1,2)', '(3,4)' ) → (1, 2),(3, 4)</code>
<code>cube_inter</code>	<code>cube_inter ( cube, cube ) → cube</code> Produces the intersection of two cubes.	<code>cube_inter( '(1,2)', '(3,4)' ) → (3, 4),(1, 2)</code>
<code>cube_enlarge</code>	<code>cube_enlarge ( c cube, r double, n integer ) → cube</code> Increases the size of the cube by the specified radius <i>r</i> in at least <i>n</i> dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius <i>r</i> . Lower-left coordinates are decreased by <i>r</i> and upper-right coordinates are increased by <i>r</i> . If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when <i>r</i> < 0) then both coordinates are set to their average. If <i>n</i> is greater than the number of defined dimensions and the cube is being enlarged ( <i>r</i> > 0), then extra dimensions are added to make <i>n</i> altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points.	<code>cube_enlarge( '(1,2),(3,4)', 0.5, 3) → (0.5, 1.5, -0.5),(3.5, 4.5, 0.5)</code>

## F.10.4. Defaults

I believe this union:

```
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
```

```
-----  
(0, 0, 0), (2, 5, 2)  
(1 row)
```

does not contradict common sense, neither does the intersection

```
select cube_inter('(0,-1),(1,1)', '(-2),(2)');  
cube_inter  
-----  
(0, 0), (1, 0)  
(1 row)
```

In all binary operations on differently-dimensional cubes, I assume the lower-dimensional one to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2),(2,3,1)', '(0,0,0),(0,0,0)');  
cube_inter('(0,-1),(1,1)', '(-2,0),(2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0),(1,1)', '0.5,0.5');  
cube_contains  
-----  
t  
(1 row)
```

## F.10.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

## F.10.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

## F.11. dblink

`dblink` is a module that supports connections to other LightDB databases from within a database session.

**Note**

See also `postgres_fdw`, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

## dblink\_connect

`dblink_connect` — opens a persistent connection to a remote database

### Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

### Description

`dblink_connect()` establishes a connection to a remote LightDB database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as `CREATE SERVER` and `CREATE USER MAPPING`.

### Arguments

*connname*

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

*connstr*

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=lightdb password=mypasswd options=-csearch_path=`. For details see Section 32.1.1. Alternatively, the name of a foreign server.

### Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

### Notes

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

### Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
```

```
OK
(1 row)
```

```
SELECT dblink_connect('myconn', 'dbname=postgres options=-
csearch_path=');
dblink_connect
```

```
-----
OK
(1 row)
```

```
-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for
-- this to work properly
-- Otherwise, you will receive the following error from
-- dblink_connect():
-- ERROR: password is required
-- DETAIL: Non-superuser cannot connect if the server does
-- not request a password.
-- HINT: Target server's authentication method must be
-- changed.
```

```
CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS
(hostaddr '127.0.0.1', dbname 'contrib_regression');
```

```
CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS
(user 'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;
```

```
\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
dblink_connect
```

```
-----
OK
(1 row)
```

```
SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b
text, c text[]);
```

```
 a | b | c
-----+-----
 0 | a | {a0,b0,c0}
 1 | b | {a1,b1,c1}
 2 | c | {a2,b2,c2}
 3 | d | {a3,b3,c3}
 4 | e | {a4,b4,c4}
 5 | f | {a5,b5,c5}
 6 | g | {a6,b6,c6}
 7 | h | {a7,b7,c7}
 8 | i | {a8,b8,c8}
 9 | j | {a9,b9,c9}
10 | k | {a10,b10,c10}
(11 rows)
```

```
\c - :ORIGINAL_USER
REVOKE USAGE ON FOREIGN SERVER fdtest FROM regress_dblink_user;
REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
```

```
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;  
DROP USER regress_dblink_user;  
DROP SERVER fdtest;
```

## **dblink\_connect\_u**

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

### **Synopsis**

```
dblink_connect_u(text connstr) returns text  
dblink_connect_u(text connname, text connstr) returns text
```

### **Description**

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local LightDB server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/ .pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/ .pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

## dblink\_disconnect

`dblink_disconnect` — closes a persistent connection to a remote database

### Synopsis

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

### Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

### Arguments

*connname*

The name of a named connection to be closed.

### Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

### Examples

```
SELECT dblink_disconnect();
 dblink_disconnect
-----
      OK
(1 row)

SELECT dblink_disconnect('myconn');
 dblink_disconnect
-----
      OK
(1 row)
```

## dblink

`dblink` — executes a query in a remote database

## Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns
  setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof
  record
dblink(text sql [, bool fail_on_error]) returns setof record
```

## Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*connstr*

A connection info string, as previously described for `dblink_connect`.

*sql*

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

## Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise `LightDB` would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
            'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text)
WHERE proname LIKE 'bytea%';
```

The “alias” part of the FROM clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a LightDB extension.) This allows the system to understand what \* should expand to, and what pronomine in the WHERE clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the FROM clause. The column names need not match, however, and dblink does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the FROM clause.

## Notes

A convenient way to use dblink with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select pronomine, prosrc from pg_proc')
  AS t1(pronomine name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE pronomine LIKE 'bytea%';
```

## Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                    'select pronomine, prosrc from pg_proc')
  AS t1(pronomine name, prosrc text) WHERE pronomine LIKE 'bytea%';
 pronomine |   prosrc
-----+-----
 byteacat  | byteacat

```

## dblink\_exec

`dblink_exec` — executes a command in a remote database

## Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns
  text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns
  text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

## Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*connstr*

A connection info string, as previously described for `dblink_connect`.

*sql*

The SQL command that you wish to execute in the remote database, for example `insert into foo values(0, 'a', '{"a0","b0","c0"}')`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

## Return Value

Returns status, either the command's status string or `ERROR`.

## Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
 dblink_connect
-----
OK
(1 row)
```

```
SELECT dblink_exec('insert into foo values(21, 'z',
  '{"a0","b0","c0"}');');
  dblink_exec
-----
INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
  dblink_connect
-----
OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, 'z',
  '{"a0","b0","c0"}');');
  dblink_exec
-----
INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values
  ('foo'),false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-
null constraint

  dblink_exec
-----
ERROR
(1 row)
```

## dblink\_open

`dblink_open` — opens a cursor in a remote database

### Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error])
  returns text
dblink_open(text connname, text cursorname, text sql [, bool
  fail_on_error]) returns text
```

### Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

### Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name to assign to this cursor.

*sql*

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function's return value is set to `ERROR`.

### Return Value

Returns status, either `OK` or `ERROR`.

### Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

### Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

-----

OK  
(1 row)

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');  
dblink_open
```

-----

OK  
(1 row)

## dblink\_fetch

`dblink_fetch` — returns rows from an open cursor in a remote database

## Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error])
  returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool
  fail_on_error]) returns setof record
```

## Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to fetch from.

*howmany*

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

## Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

## Notes

On a mismatch between the number of return columns specified in the FROM clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote FETCH has been done.

## Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
```

```
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc
where proname like ''bytea%'');
dblink_open
```

```
-----
OK
(1 row)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source
text);
```

```
funcname | source
-----+-----
byteacat | byteacat

## dblink\_close

`dblink_close` — closes a cursor in a remote database

## Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error])
returns text
```

## Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to close.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to ERROR.

## Return Value

Returns status, either OK or ERROR.

## Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching COMMIT.

## Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
OK
(1 row)

SELECT dblink_close('foo');
```

dblink\_close

-----  
OK  
(1 row)

## **dblink\_get\_connections**

`dblink_get_connections` — returns the names of all open named dblink connections

### **Synopsis**

```
dblink_get_connections() returns text[]
```

### **Description**

`dblink_get_connections` returns an array of the names of all open named dblink connections.

### **Return Value**

Returns a text array of connection names, or NULL if none.

### **Examples**

```
SELECT dblink_get_connections();
```

## **dblink\_error\_message**

`dblink_error_message` — gets last error message on the named connection

### **Synopsis**

```
dblink_error_message(text connname) returns text
```

### **Description**

`dblink_error_message` fetches the most recent remote error message for a given connection.

### **Arguments**

*connname*

Name of the connection to use.

### **Return Value**

Returns last error message, or OK if there has been no error in this connection.

### **Notes**

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

### **Examples**

```
SELECT dblink_error_message('dtest1');
```

## **dblink\_send\_query**

`dblink_send_query` — sends an async query to a remote database

### **Synopsis**

```
dblink_send_query(text connname, text sql) returns int
```

### **Description**

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

### **Arguments**

*connname*

Name of the connection to use.

*sql*

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

### **Return Value**

Returns 1 if the query was successfully dispatched, 0 otherwise.

### **Examples**

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

## **dblink\_is\_busy**

`dblink_is_busy` — checks if connection is busy with an async query

### **Synopsis**

```
dblink_is_busy(text connname) returns int
```

### **Description**

`dblink_is_busy` tests whether an async query is in progress.

### **Arguments**

*connname*

Name of the connection to check.

### **Return Value**

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

### **Examples**

```
SELECT dblink_is_busy('dtest1');
```

## dblink\_get\_notify

dblink\_get\_notify — retrieve async notifications on a connection

### Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int,
  extra text)
dblink_get_notify(text connname) returns setof (notify_name text,
  be_pid int, extra text)
```

### Description

dblink\_get\_notify retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink\_exec. For details see LISTEN and NOTIFY.

### Arguments

*connname*

The name of a named connection to get notifications on.

### Return Value

Returns setof (notify\_name text, be\_pid int, extra text), or an empty set if none.

### Examples

```
SELECT dblink_exec('LISTEN virtual');
dblink_exec
-----
LISTEN
(1 row)

SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
(0 rows)

NOTIFY virtual;
NOTIFY

SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
 virtual    | 1229  |
(1 row)
```

## dblink\_get\_result

`dblink_get_result` — gets an async query result

### Synopsis

```
dblink_get_result(text connname [, bool fail_on_error]) returns
  setof record
```

### Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

### Arguments

*connname*

Name of the connection to use.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

### Return Value

For an async query (that is, a SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, a SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling FROM clause.

### Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

### Examples

```
contrib_regression=# SELECT dblink_connect('dtest1',
  'dbname=contrib_regression');
dblink_connect
-----
```

OK  
(1 row)

```
contrib_regression=# SELECT * FROM
contrib_regression=# dblink_send_query('dtest1', 'select * from foo
where f1 < 3') AS t1;
t1
```

```
----
 1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 |      f3
```

```
----+-----+-----
 0 | a  | {a0,b0,c0}
 1 | b  | {a1,b1,c1}
 2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 | f3
```

```
----+-----+-----
(0 rows)
```

```
contrib_regression=# SELECT * FROM
contrib_regression=# dblink_send_query('dtest1', 'select * from foo
where f1 < 3; select * from foo where f1 > 6') AS t1;
t1
```

```
----
 1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 |      f3
```

```
----+-----+-----
 0 | a  | {a0,b0,c0}
 1 | b  | {a1,b1,c1}
 2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 |      f3
```

```
----+-----+-----
 7 | h  | {a7,b7,c7}
 8 | i  | {a8,b8,c8}
 9 | j  | {a9,b9,c9}
10 | k  | {a10,b10,c10}
(4 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 | f3
```

```
----+-----+-----
(0 rows)
```

## **dblink\_cancel\_query**

`dblink_cancel_query` — cancels any active query on the named connection

### **Synopsis**

```
dblink_cancel_query(text connname) returns text
```

### **Description**

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

### **Arguments**

*connname*

Name of the connection to use.

### **Return Value**

Returns OK if the cancel request has been sent, or the text of an error message on failure.

### **Examples**

```
SELECT dblink_cancel_query('dtest1');
```

## dblink\_get\_pkey

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

## Synopsis

```
dblink_get_pkey(text relname) returns setof dblink_pkey_results
```

## Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

## Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

## Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

## Examples

```
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE  
  
SELECT * FROM dblink_get_pkey('foobar');  
 position | colname  
-----+-----  
         1 | f1  
         2 | f2  
         3 | f3  
(3 rows)
```

## dblink\_build\_sql\_insert

`dblink_build_sql_insert` — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

### Synopsis

```
dblink_build_sql_insert(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL INSERT command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*src\_pk\_att\_vals\_array*

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be placed in the resulting INSERT command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of LightDB 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous

versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

## Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}',
    '{"1", "b'a"}');
          dblink_build_sql_insert
-----
INSERT INTO foo(f1,f2,f3) VALUES('1','b'a','1')
(1 row)
```

## dblink\_build\_sql\_delete

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

### Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds a SQL DELETE command that will delete the row with the given primary key values.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of LightDB 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

### Examples

```
SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, '{"1", "b"}');  
      dblink_build_sql_delete
```

```
-----  
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'  
(1 row)
```

## dblink\_build\_sql\_update

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

### Synopsis

```
dblink_build_sql_update(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*src\_pk\_att\_vals\_array*

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of LightDB 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

## Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}',
    '{"1", "b"}');
          dblink_build_sql_update
-----
UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
(1 row)
```

## F.12. dict\_int

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.12.1. Configuration

The dictionary accepts three options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The `absval` parameter specifies whether leading “+” or “-” signs should be removed from integer words. The default is `false`. When `true`, the sign is removed before `maxlen` is applied.

### F.12.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG
= true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
      ts_lexize
-----
{123456}
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
ALTER MAPPING FOR int, uint WITH intdict;
```

## F.13. dict\_xsyn

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

### F.13.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.
- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$(SHAREDIR)/tsearch_data/` (where `$(SHAREDIR)` means the LightDB installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

```
word syn1 syn2 syn3
```

- The sharp (#) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$(SHAREDIR)/tsearch_data/`, for an example.

### F.13.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
       ts_lexize
-----
{syn1,syn2,syn3}
```

```

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
      KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'word');
      ts_lexize
-----
 {word,syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
      KEEPORIG=false, MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
      ts_lexize
-----
 {syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
      KEEPORIG=true, MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
      ts_lexize
-----
 {word}

```

Real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```

ALTER TEXT SEARCH CONFIGURATION english
      ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;

```

## F.14. file\_fdw

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see `COPY` for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

`filename`

Specifies the file to be read. Relative paths are relative to the data directory. Either `filename` or `program` must be specified, but not both.

`program`

Specifies the command to be executed. The standard output of this command will be read as though `COPY FROM PROGRAM` were used. Either `program` or `filename` must be specified, but not both.

`format`

Specifies the data format, the same as `COPY`'s `FORMAT` option.

`header`

Specifies whether the data has a header line, the same as `COPY`'s `HEADER` option.

`delimiter`

Specifies the data delimiter character, the same as COPY's DELIMITER option.

`quote`

Specifies the data quote character, the same as COPY's QUOTE option.

`escape`

Specifies the data escape character, the same as COPY's ESCAPE option.

`null`

Specifies the data null string, the same as COPY's NULL option.

`encoding`

Specifies the data encoding, the same as COPY's ENCODING option.

Note that while COPY allows options such as HEADER to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate COPY options typically written without a value, you can pass the value TRUE, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

`force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level null option). This has the same effect as listing the column in COPY's FORCE\_NOT\_NULL option.

`force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as NULL even if the value is quoted. Without this option, only unquoted values matching the null string are returned as NULL. This has the same effect as listing the column in COPY's FORCE\_NULL option.

COPY's FORCE\_QUOTE option is currently not supported by `file_fdw`.

These options can only be specified for a foreign table or its columns, not in the options of the `file_fdw` foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the default role `pg_read_server_files` (to use a filename) or the default role `pg_execute_server_program` (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the `program` option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using `file_fdw`, EXPLAIN shows the name of the file to be read or program to be run. For a file, unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

### **Example F.1. Create a Foreign Table for LightDB CSV Logs**

One of the obvious uses for `file_fdw` is to make the LightDB activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call `ltlog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER ltlog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE ltlog (  
  log_time timestamp(3) with time zone,  
  user_name text,  
  database_name text,  
  process_id integer,  
  connection_from text,  
  session_id text,  
  session_line_num bigint,  
  command_tag text,  
  session_start_time timestamp with time zone,  
  virtual_transaction_id text,  
  transaction_id bigint,  
  error_severity text,  
  sql_state_code text,  
  message text,  
  detail text,  
  hint text,  
  internal_query text,  
  internal_query_pos integer,  
  context text,  
  query text,  
  query_pos integer,  
  location text,  
  application_name text,  
  backend_type text  
) SERVER ltlog  
OPTIONS ( filename 'log/ltlog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

## F.15. fuzzystmatch

The `fuzzystmatch` module provides several functions to determine similarities and distance between strings.

### Caution

At present, the `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` functions do not work well with multibyte encodings (such as UTF-8).

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

## F.15.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystrmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text  
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — `similarity` would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');  
  
SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');  
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne',  
  'Andrew');  
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne',  
  'Margaret');  
  
CREATE TABLE s (nm text);  
  
INSERT INTO s VALUES ('john');  
INSERT INTO s VALUES ('joan');  
INSERT INTO s VALUES ('wobbly');  
INSERT INTO s VALUES ('jack');  
  
SELECT * FROM s WHERE soundex(nm) = soundex('john');  
  
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

## F.15.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(text source, text target, int ins_cost, int del_cost,  
  int sub_cost) returns int  
levenshtein(text source, text target) returns int  
levenshtein_less_equal(text source, text target, int ins_cost, int  
  del_cost, int sub_cost, int max_d) returns int  
levenshtein_less_equal(text source, text target, int max_d) returns  
  int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
 levenshtein
-----
                2
(1 row)
```

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
 levenshtein
-----
                3
(1 row)
```

```
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
 levenshtein_less_equal
-----
                                3
(1 row)
```

```
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
 levenshtein_less_equal
-----
                                4
(1 row)
```

### F.15.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

`metaphone(text source, int max_output_length)` returns `text`

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----
        KM
(1 row)
```

### F.15.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially

they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```
dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text
```

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
 dmetaphone
-----
      KMP
(1 row)
```

## F.16. hstore

This module implements the `hstore` data type for storing sets of key/value pairs within a single LightDB value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.16.1. hstore External Representation

The text representation of an `hstore`, used for input and output, includes zero or more *key => value* pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=`s or `>`s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
 hstore
-----
"a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “`NULL`”.

**Note**

Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

**F.16.2. hstore Operators and Functions**

The operators provided by the `hstore` module are shown in Table F.5, the functions in Table F.6.

**Table F.5. hstore Operators**

<b>Operator</b>	<b>Description</b>	<b>Example(s)</b>
<code>hstore -&gt; text → text</code>	Returns value associated with given key, or NULL if not present.	<code>'a=&gt;x, b=&gt;y'::hstore -&gt; 'a' → x</code>
<code>hstore -&gt; text[] → text[]</code>	Returns values associated with given keys, or NULL if not present.	<code>'a=&gt;x, b=&gt;y, c=&gt;z'::hstore -&gt; ARRAY['c','a'] → {"z","x"}</code>
<code>hstore    hstore → hstore</code>	Concatenates two <code>hstore</code> s.	<code>'a=&gt;b, c=&gt;d'::hstore    'c=&gt;x, d=&gt;q'::hstore → "a"=&gt;"b", "c"=&gt;"x", "d"=&gt;"q"</code>
<code>hstore ? text → boolean</code>	Does <code>hstore</code> contain key?	<code>'a=&gt;1'::hstore ? 'a' → t</code>
<code>hstore ?&amp; text[] → boolean</code>	Does <code>hstore</code> contain all the specified keys?	<code>'a=&gt;1,b=&gt;2'::hstore ?&amp; ARRAY['a','b'] → t</code>
<code>hstore ?  text[] → boolean</code>	Does <code>hstore</code> contain any of the specified keys?	<code>'a=&gt;1,b=&gt;2'::hstore ?  ARRAY['b','c'] → t</code>
<code>hstore @&gt; hstore → boolean</code>	Does left operand contain right?	<code>'a=&gt;b, b=&gt;1, c=&gt;NULL'::hstore @&gt; 'b=&gt;1' → t</code>
<code>hstore &lt;@ hstore → boolean</code>	Is left operand contained in right?	<code>'a=&gt;c'::hstore &lt;@ 'a=&gt;b, b=&gt;1, c=&gt;NULL' → f</code>
<code>hstore - text → hstore</code>		

<b>Operator</b>	<b>Description</b> <b>Example(s)</b>
	Deletes key from left operand. <code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - 'b'::text → "a"=&gt;"1", "c"=&gt;"3"</code>
<code>hstore - text[] → hstore</code>	Deletes keys from left operand. <code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - ARRAY['a','b'] → "c"=&gt;"3"</code>
<code>hstore - hstore → hstore</code>	Deletes pairs from left operand that match pairs in the right operand. <code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - 'a=&gt;4, b=&gt;2'::hstore → "a"=&gt;"1", "c"=&gt;"3"</code>
<code>anyelement #= hstore → anyelement</code>	Replaces fields in the left operand (which must be a composite type) with matching values from hstore. <code>ROW(1,3) #= 'f1=&gt;11'::hstore → (11,3)</code>
<code>%% hstore → text[]</code>	Converts hstore to an array of alternating keys and values. <code>%% 'a=&gt;foo, b=&gt;bar'::hstore → {a,foo,b,bar}</code>
<code>%# hstore → text[]</code>	Converts hstore to a two-dimensional key/value array. <code>%# 'a=&gt;foo, b=&gt;bar'::hstore → {{a,foo},{b,bar}}</code>

**Note**

Prior to LightDB 8.2, the containment operators @> and <@ were called @ and ~, respectively. These names are still available, but are deprecated and will eventually be removed. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!

**Table F.6. hstore Functions**

<b>Function</b>	<b>Description</b> <b>Example(s)</b>
<code>hstore ( record ) → hstore</code>	Constructs an hstore from a record or row. <code>hstore(ROW(1,2)) → "f1"=&gt;"1", "f2"=&gt;"2"</code>
<code>hstore ( text[] ) → hstore</code>	Constructs an hstore from an array, which may be either a key/value array, or a two-dimensional array. <code>hstore(ARRAY['a','1','b','2']) → "a"=&gt;"1", "b"=&gt;"2"</code> <code>hstore(ARRAY[['c','3'],['d','4']]) → "c"=&gt;"3", "d"=&gt;"4"</code>
<code>hstore ( text[], text[] ) → hstore</code>	Constructs an hstore from separate key and value arrays. <code>hstore(ARRAY['a','b'], ARRAY['1','2']) → "a"=&gt;"1", "b"=&gt;"2"</code>

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
<code>hstore ( text, text ) → hstore</code>	Makes a single-item hstore.	<code>hstore( 'a', 'b' ) → "a"=&gt;"b"</code>
<code>akeys ( hstore ) → text [ ]</code>	Extracts an hstore's keys as an array.	<code>akeys( 'a=&gt;1,b=&gt;2' ) → {a,b}</code>
<code>skeys ( hstore ) → setof text</code>	Extracts an hstore's keys as a set.	<code>skeys( 'a=&gt;1,b=&gt;2' ) →</code>  <code>a</code> <code>b</code>
<code>avals ( hstore ) → text [ ]</code>	Extracts an hstore's values as an array.	<code>avals( 'a=&gt;1,b=&gt;2' ) → {1,2}</code>
<code>svals ( hstore ) → setof text</code>	Extracts an hstore's values as a set.	<code>svals( 'a=&gt;1,b=&gt;2' ) →</code>  <code>1</code> <code>2</code>
<code>hstore_to_array ( hstore ) → text [ ]</code>	Extracts an hstore's keys and values as an array of alternating keys and values.	<code>hstore_to_array( 'a=&gt;1,b=&gt;2' ) → {a,1,b,2}</code>
<code>hstore_to_matrix ( hstore ) → text [ ]</code>	Extracts an hstore's keys and values as a two-dimensional array.	<code>hstore_to_matrix( 'a=&gt;1,b=&gt;2' ) → {{a,1},{b,2}}</code>
<code>hstore_to_json ( hstore ) → json</code>	Converts an hstore to a json value, converting all non-null values to JSON strings. This function is used implicitly when an hstore value is cast to json.	<code>hstore_to_json( "a key"=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4' ) → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</code>
<code>hstore_to_jsonb ( hstore ) → jsonb</code>	Converts an hstore to a jsonb value, converting all non-null values to JSON strings. This function is used implicitly when an hstore value is cast to jsonb.	<code>hstore_to_jsonb( "a key"=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4' ) → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</code>
<code>hstore_to_json_loose ( hstore ) → json</code>		

Function	Description	Example(s)						
	Converts an hstore to a json value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.	<pre>hstore_to_json_loose('"a key"=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</pre>						
	Converts an hstore to a jsonb value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.	<pre>hstore_to_jsonb_loose('"a key"=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</pre>						
	Extracts a subset of an hstore containing only the specified keys.	<pre>slice('a=&gt;1,b=&gt;2,c=&gt;3'::hstore, ARRAY['b','c','x']) → "b"=&gt;"2", "c"=&gt;"3"</pre>						
	Extracts an hstore's keys and values as a set of records.	<pre>select * from each('a=&gt;1,b=&gt;2') →</pre> <table border="1" style="margin-left: 40px;"> <thead> <tr> <th>key</th> <th>value</th> </tr> </thead> <tbody> <tr> <td>a</td> <td>1</td> </tr> <tr> <td>b</td> <td>2</td> </tr> </tbody> </table>	key	value	a	1	b	2
key	value							
a	1							
b	2							
	Does hstore contain key?	<pre>exist('a=&gt;1', 'a') → t</pre>						
	Does hstore contain a non-NULL value for key?	<pre>defined('a=&gt;NULL', 'a') → f</pre>						
	Deletes pair with matching key.	<pre>delete('a=&gt;1,b=&gt;2', 'b') → "a"=&gt;"1"</pre>						
	Deletes pairs with matching keys.	<pre>delete('a=&gt;1,b=&gt;2,c=&gt;3', ARRAY['a','b']) → "c"=&gt;"3"</pre>						
	Deletes pairs matching those in the second argument.	<pre>delete('a=&gt;1,b=&gt;2', 'a=&gt;4,b=&gt;2'::hstore) → "a"=&gt;"1"</pre>						
	Replaces fields in the left operand (which must be a composite type) with matching values from hstore.	<pre>populate_record( anyelement, hstore ) → anyelement</pre>						

Function
<b>Description</b> <b>Example(s)</b>
<code>populate_record(ROW(1,2), 'f1=&gt;42'::hstore) → (42,2)</code>

## F.16.3. Indexes

`hstore` has GiST and GIN index support for the `@>`, `?`, `?&` and `?|` operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);
```

```
CREATE INDEX hidx ON testhstore USING GIN (h);
```

`gist_hstore_ops` GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX hidx ON testhstore USING GIST (h
gist_hstore_ops(siglen=32));
```

`hstore` also supports `btree` or `hash` indexes for the `=` operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP BY`, `ORDER BY` or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for `=` comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);
```

```
CREATE INDEX hidx ON testhstore USING HASH (h);
```

## F.16.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h = h || hstore('c', '3');
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT hstore(t) FROM test AS t;
           hstore
```

```
-----
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an hstore to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test,
                              '"col1"=>"456", "col2"=>"zzz"');

 col1 | col2 | col3
-----+-----+-----
  456 | zzz  |
(1 row)
```

Modify an existing record using the values from an hstore:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;

 col1 | col2 | col3
-----+-----+-----
  123 | foo  | baz
(1 row)
```

## F.16.5. Statistics

The hstore type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;

 key      | count
-----+-----
 line     |    883
 query    |    207
 pos      |    203
 node     |    202
 space    |    197
 status   |    195
 public   |    194
 title    |    190
 org      |    189
.....
```

## F.16.6. Compatibility

As of LightDB 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol  
|| '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

## F.16.7. Transforms

<p style="text-align: center;"><b>Caution</b></p> <p>It is strongly recommended that the transform extensions be installed in the same schema as <code>hstore</code>. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.</p>
--

## F.16.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

## F.17. intagg

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

### F.17.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

## F.17.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT
  REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id =
  one_to_many.right)
  WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
  SELECT left, int_array_aggregate(right) AS right
  FROM one_to_many
  GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an EXPLAIN showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
  ( SELECT left, int_array_enum(right) AS right
    FROM summary JOIN (SELECT left FROM left_table WHERE left
  = item) AS lefts
    ON (summary.left = lefts.left)
  ) AS list
  GROUP BY right
  ORDER BY count DESC;
```

## F.18. intarray

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

### F.18.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in Table F.7, the operators in Table F.8.

**Table F.7. intarray Functions**

Function	Description	Example(s)
<code>icount ( integer[] )</code>	<code>→ integer</code> Returns the number of elements in the array.	<code>icount ( '{1,2,3}' :: integer[] ) → 3</code>
<code>sort ( integer[], dir text )</code>	<code>→ integer[]</code> Sorts the array in either ascending or descending order. <i>dir</i> must be <i>asc</i> or <i>desc</i> .	<code>sort ( '{1,3,2}' :: integer[], 'desc' ) → {3,2,1}</code>
<code>sort ( integer[] )</code>	<code>→ integer[]</code>	
<code>sort_asc ( integer[] )</code>	<code>→ integer[]</code> Sorts in ascending order.	<code>sort ( array[11,77,44] ) → {11,44,77}</code>
<code>sort_desc ( integer[] )</code>	<code>→ integer[]</code> Sorts in descending order.	<code>sort_desc ( array[11,77,44] ) → {77,44,11}</code>
<code>uniq ( integer[] )</code>	<code>→ integer[]</code> Removes adjacent duplicates. Often used with <code>sort</code> to remove all duplicates.	<code>uniq ( '{1,2,2,3,1,1}' :: integer[] ) → {1,2,3,1}</code> <code>uniq ( sort ( '{1,2,3,2,1}' :: integer[] ) ) → {1,2,3}</code>
<code>idx ( integer[], item integer )</code>	<code>→ integer</code> Returns index of the first array element matching <i>item</i> , or 0 if no match.	<code>idx ( array[11,22,33,22,11], 22 ) → 2</code>
<code>subarray ( integer[], start integer, len integer )</code>	<code>→ integer[]</code> Extracts the portion of the array starting at position <i>start</i> , with <i>len</i> elements.	<code>subarray ( '{1,2,3,2,1}' :: integer[], 2, 3 ) → {2,3,2}</code>
<code>subarray ( integer[], start integer )</code>	<code>→ integer[]</code> Extracts the portion of the array starting at position <i>start</i> .	<code>subarray ( '{1,2,3,2,1}' :: integer[], 2 ) → {2,3,2,1}</code>
<code>intset ( integer )</code>	<code>→ integer[]</code>	

<b>Function</b>
<b>Description</b> <b>Example(s)</b>
Makes a single-element array. <code>intset(42) → {42}</code>

**Table F.8. intarray Operators**

<b>Operator</b>
<b>Description</b>
<code>integer[] &amp;&amp; integer[] → boolean</code> Do arrays overlap (have at least one element in common)?
<code>integer[] @&gt; integer[] → boolean</code> Does left array contain right array?
<code>integer[] &lt;@ integer[] → boolean</code> Is left array contained in right array?
<code># integer[] → integer</code> Returns the number of elements in the array.
<code>integer[] # integer → integer</code> Returns index of the first array element matching the right argument, or 0 if no match. (Same as <code>idx</code> function.)
<code>integer[] + integer → integer[]</code> Adds element to end of array.
<code>integer[] + integer[] → integer[]</code> Concatenates the arrays.
<code>integer[] - integer → integer[]</code> Removes entries matching the right argument from the array.
<code>integer[] - integer[] → integer[]</code> Removes elements of the right array from the left array.
<code>integer[]   integer → integer[]</code> Computes the union of the arguments.
<code>integer[]   integer[] → integer[]</code> Computes the union of the arguments.
<code>integer[] &amp; integer[] → integer[]</code> Computes the intersection of the arguments.
<code>integer[] @@ query_int → boolean</code> Does array satisfy query? (see below)
<code>query_int ~~ integer[] → boolean</code> Does array satisfy query? (commutator of @@)

(Before LightDB 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The operators `&&`, `@>` and `<@` are equivalent to LightDB's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The @@ and ~~ operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators & (AND), | (OR), and ! (NOT). Parentheses can be used as needed. For example, the query `1 & (2 | 3)` matches arrays that contain 1 and also contain either 2 or 3.

## F.18.2. Index Support

`intarray` provides index support for the &&, @>, <@, and @@ operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops` supporting the same operators.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

## F.18.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections
  gist__intbig_ops (siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@
  '1&2'::query_int;
```

## F.18.4. Benchmark

The source directory `contrib/intarray/bench` contains a benchmark test suite, which can be run against an installed LightDB server. (It also requires `DBD:Pg` to be installed.) To run:

```
cd ../contrib/intarray/bench
```

```
createdb TEST
ltsql -c "CREATE EXTENSION intarray" TEST
./create_test.pl | ltsql TEST
./bench.pl
```

The `bench.pl` script has numerous options, which are displayed when it is run without any arguments.

## F.18.5. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

## F.19. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.19.1. Data Types

Table F.9 shows the data types provided by the `isn` module.

**Table F.9. isn Data Types**

Data Type	Description
EAN13	European Article Numbers, always displayed in the EAN13 display format
ISBN13	International Standard Book Numbers to be displayed in the new EAN13 display format
ISMN13	International Standard Music Numbers to be displayed in the new EAN13 display format
ISSN13	International Standard Serial Numbers to be displayed in the new EAN13 display format
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).

3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The ISBN, ISMN, and ISSN types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The EAN13, ISBN13, ISMN13 and ISSN13 types will always display the long version of the ISxN (EAN13).

## F.19.2. Casts

The `isn` module provides the following pairs of type casts:

- ISBN13 <=> EAN13
- ISMN13 <=> EAN13
- ISSN13 <=> EAN13
- ISBN <=> EAN13
- ISMN <=> EAN13
- ISSN <=> EAN13
- UPC <=> EAN13
- ISBN <=> ISBN13
- ISMN <=> ISMN13
- ISSN <=> ISSN13

When casting from EAN13 to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

## F.19.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in Table F.10. In this table, `isn` means any one of the module's data types.

**Table F.10. `isn` Functions**

Function	Description
<code>isn_weak ( boolean ) → boolean</code>	Sets the weak input mode, and returns new setting.
<code>isn_weak () → boolean</code>	Returns the current status of the weak mode.

Function	Description
<code>make_valid(isn) → isn</code>	Validates an invalid number (clears the invalid flag).
<code>is_valid(isn) → boolean</code>	Checks for the presence of the invalid flag.

*Weak* mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the ! character at the end of the number.

Another special feature is that during input, you can write ? in place of the check digit, and the correct check digit will be inserted automatically.

## F.19.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select
  isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');
```

```
--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

## F.19.5. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>
- <https://www.issn.org/>
- <https://www.ismn-international.org/>
- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- <https://www.gs1.org/standards/id-keys>
- [https://en.wikipedia.org/wiki/List\\_of\\_ISBN\\_identifier\\_groups](https://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups)
- <https://www.isbn-international.org/content/isbn-users-manual>
- [https://en.wikipedia.org/wiki/International\\_Standard\\_Music\\_Number](https://en.wikipedia.org/wiki/International_Standard_Music_Number)
- <https://www.ismn-international.org/ranges.html>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

## F.19.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

## F.20. lo

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.20.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As LightDB stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for LightDB-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a domain of the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

## F.20.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

## F.20.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the `vacuumlo` module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

## F.20.4. Author

Peter Mount <peter@retep.org.uk>

## F.21. `lt_buffercache`

The `lt_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default, use is restricted to superusers and members of the `pg_monitor` role. Access may be granted to others using `GRANT`.

## F.21.1. The `pg_buffercache` View

The definitions of the columns exposed by the view are shown in Table F.11.

**Table F.11. `pg_buffercache` Columns**

Column Type	Description
<code>bufferid integer</code>	ID, in the range <code>1..shared_buffers</code>
<code>relfilenode oid (references pg_class.relfilenode)</code>	Filenode number of the relation
<code>reltablespace oid (references pg_tablespace.oid)</code>	Tablespace OID of the relation
<code>reldatabase oid (references pg_database.oid)</code>	Database OID of the relation
<code>relforknumber smallint</code>	Fork number within the relation; see <code>include/common/relpath.h</code>
<code>relblocknumber bigint</code>	Page number within the relation
<code>isdirty boolean</code>	Is the page dirty?
<code>usagecount smallint</code>	Clock-sweep access count
<code>pinning_backends integer</code>	Number of backends pinning this buffer

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

## F.21.2. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
              FROM pg_buffercache b JOIN pg_class c
              ON b.relfilenode = pg_relation_filenode(c.oid) AND
                 b.reldatabase IN (0, (SELECT oid FROM pg_database
```

```

WHERE datname =
current_database()))
JOIN pg_namespace n ON n.oid = c.relnamespace
GROUP BY n.nspname, c.relname
ORDER BY 3 DESC
LIMIT 9;

```

nspname	relname	buffers
public	delete_test_table	593
public	delete_test_table_pkey	494
pg_catalog	pg_attribute	472
public	quad_poly_tbl	353
public	tenk2	349
public	tenk1	349
public	gin_test_idx	306
pg_catalog	pg_largeobject	206
public	gin_test_tbl	188

(9 rows)

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

## F.22. It\_bulkload

It\_bulkload is a high speed data loading tool for LightDB.

It\_bulkload is designed to load huge amount of data to a database. You can load data to table bypassing LightDB shared buffers.

It\_bulkload also has some ETL features; input data validation and data transformation.

### F.22.1. Synopsis

```
It_bulkload [ OPTIONS ] [ controlfile ]
```

### F.22.2. Description

It\_bulkload is designed to load huge amount of data to a database. You can choose whether database constraints are checked and how many errors are ignored during the loading. For example, you can skip integrity checks for performance when you copy data from another database to LightDB. On the other hand, you can enable constraint checks when loading unclean data.

It\_bulkload can convert the load data into the binary file which can be used as an input file of It\_bulkload. If you check whether the load data is valid when converting it into the binary file, you can skip the check when loading it from the binary file to a table.

### F.22.3. Usage

You can use It\_bulkload by the following three steps:

1. Edit control file "sample\_csv.ctl" or "sample\_bin.ctl" that includes settings for data loading. You can specify table name, absolute path for input file, description of the input file, and so on.

2. Assume there is a directory \$LTDATA/lt\_bulkload, in that load status files are created.
3. Execute command with a control file as argument. Relative path is available for the argument.

```
$ lt_bulkload sample_csv.ctl
NOTICE: BULK LOAD START
NOTICE: BULK LOAD END
 0 Rows skipped.
 8 Rows successfully loaded.
 0 Rows not loaded due to parse errors.
 0 Rows not loaded due to duplicate errors.
 0 Rows replaced with new rows.
```

## F.22.4. Options

lt\_bulkload has the following command line options:

### F.22.4.1. Load Options

```
-i INPUT
--input=INPUT
--infile=INPUT
Source to load data from. Same as "INPUT" in
control files.
-O OUTPUT
--output=OUTPUT
Destination to load data to. Same as "OUTPUT" in
control files.
-l LOGFILE
--logfile=LOGFILE
A path to write the result log. Same as "LOGFILE"
in control files.
-P PARSE_BADFILE
--parse-badfile=PARSE_BADFILE
A path to write bad records that cannot be parsed
correctly. Same as "PARSE_BADFILE" in control files.
-u DUPLICATE_BADFILE
--duplicate-badfile=DUPLICATE_BADFILE
A path to write bad records that conflict
with unique constraints during index rebuild. Same as
"DUPLICATE_BADFILE" in control files.
-o "key=val"
--option="key=val"
Any options available in the control file. You can
pass multiple options.
```

### F.22.4.2. Connection Options

Options to connect to servers.

```
-d dbname
--dbname dbname
Specifies the name of the database to be connected.
If this is not specified, the database name is read from the
```

environment variable `LTDATABASE`. If that is not set, the user name specified for the connection is used.

`-h host`

`--host host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`

`--username username`

User name to connect as.

`-W`

`--password`

Force `lt_bulkload` to prompt for a password before connecting to a database.

This option is never essential, since `lt_bulkload` will automatically prompt for a password if the server demands password authentication. However, `vacuumdb` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

### F.22.4.3. Generic Options

`-e`

`--echo`

Echo commands sent to server.

`-E`

`--elevel`

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

`--help`

Show usage of the program.

`--version`

Show the version number of the program.

## F.22.5. Control Files

You can specify the following load options. Control files can be specified with an absolute path or a relative path. If you specify it by a relative path, it will be relative to the current working directory executing `lt_bulkload` command. If you don't specify a control file, you should pass required options through command line arguments for `lt_bulkload`.

Following parameters are available in control files. Characters after `"#"` are ignored as comments in each line.

### F.22.5.1. Common

`TYPE = CSV | BINARY | FIXED | FUNCTION`

The type of input data. The default is `CSV`.

- `CSV` : load from a text file in `CSV` format

- **BINARY | FIXED** : load from a fixed binary file
- **FUNCTION** : load from a result set from a function.

If you use it, **INPUT** must be an expression to call a function.

**INPUT | INFILE** = path | stdin | [ schemaname. ] function\_name (argvalue, ...)

Source to load data from. Always required. The value is treated as following depending on the **TYPE** option:

- **A file in the server**: This is a file path in server. If it is a relative path, it will be relative from the control file when specified in the control file, or will be relative from current working directory when specified in command line arguments. The user of LightDB server must have read permission to the file. It is available only when "**TYPE=CSV**" or "**TYPE=BINARY**".
- **Standard input to It\_bulkload command**: "**INPUT=stdin**" means It\_bulkload will read data from the standard input of It\_bulkload client program through network. You should use this form when the input file and database is in different servers. It is available only when "**TYPE=CSV**" or "**TYPE=BINARY**".
- **A SQL function**: Specify a SQL function with arguments that returns set of input data. It is available only when "**TYPE=FUNCTION**". You can use not only build-in functions but also any user-defined functions. The defined functions should return the type as **SETOF sometype**, or as **RETURNS TABLE(columns)**. Note that you specify attributes types if you use sometype. Because there is a case that assignment cast to cstring type which It\_bulkload uses internally, doesn't be permitted. Note that you might need to develop those function with C language instead of PL/pgSQL because the function must use **SFRM\_ValuePerCall** mode for streaming loading.

Here is an example of user-defined function.

```

                                $ CREATE TYPE sample_type AS (sum
integer, name char(10));
                                $ CREATE FUNCTION sample_function()
RETURNS SETOF sample_type
                                AS $$ SELECT id1 + id2,
upper(name) FROM INPUT_TABLE $$
                                LANGUAGE SQL;

```

Here is an example of a control file.

```

TABLE = sample_table
TYPE = FUNCTION
WRITER = DIRECT
INPUT = sample_function()      #
if to use the user-defined function
                                #INPUT = generate_series(1, 1000)
# if to use the build-in function, which generate sequential
numbers from 1 to 1000

```

**WRITER | LOADER** = **DIRECT | BUFFERED | BINARY | PARALLEL**

The method to load data. The default is **DIRECT**.

- **DIRECT** : Load data directly to table. Bypass the shared buffers and skip WAL logging, but need the own recovery procedure. This is the default, and original older version's mode.

- **BUFFERED** : Load data to table via shared buffers. Use shared buffers, write WALs, and use the original LightDB WAL recovery.
- **BINARY** : Convert data into the binary file which can be used as an input file to load from. Create a sample of the control file necessary to load the output binary file. This sample file is created in the same directory as the binary file.
- **PARALLEL** : Same as "WRITER=DIRECT" and "MULTI\_PROCESS=YES". If PARALLEL is specified, MULTI\_PROCESS is ignored. If password authentication is configured to the database to load, you have to set up the password file. See Restrictions for details.

OUTPUT | TABLE = { [ schema\_name. ] table\_name | outfile }

Destination to load data to. Always required. The value is treated as following depending on the WRITER (or LOADER) option:

- A table to load to: Specify the table to load to. If schema\_name is omitted, the first matching table in the search\_path is used. You can load data to a table only if WRITER is DIRECT, BUFFERED or PARALLEL.
- A file in the server: Specify the path of the output file in the server. If it's a relative path, it will be interpreted in the same way as INPUT option. The OS user running LightDB must have write permission to the parent directory of the specified file. You can load (convert) data to a file only if WRITER is BINARY.

SKIP | OFFSET = n

The number of skip input rows. The default is 0. You must not specify both "TYPE=FUNCTION" and SKIP at the same time.

LIMIT | LOAD = n

The number of rows to load. The default is INFINITE, i.e., all of data will be loaded. This option is available even if you use TYPE=FUNCTION.

ENCODING = encoding

Specify the encoding of the input data. Check whether the specified encoding is valid, and convert the input data to the database encoding if needed. By default, the encoding of the input data is neither verified nor converted. If you can be sure that the input data is encoded in the database encoding, you can reduce the load time by not specifying this option, and by skipping encoding verification and conversion. Note that client\_encoding is used as the encoding of the input data by default only if INPUT is stdin. You must not specify both "TYPE=FUNCTION" and ENCODING at the same time.

Here are option values and actual behaviors:

			DB
encoding			
SQL_ASCII	not specified	non-SQL_ASCII	neither
checked nor converted	SQL_ASCII	checked nor converted	neither
checked nor converted	only checked		
DB only checked	non-SQL_ASCII,		same as
checked	non-SQL_ASCII, different from DB	checked and converted	only

`FILTER = [ schema_name. ] function_name [ (argtype, ... ) ]`

Specify the filter function to convert each row in the input file. You can omit definitions of argtype as long as the function name is unique in the database. If not specified, the input data are directly parsed as the load-target table. See also How to write FILTER functions to make FILTER functions.

You must not specify both "TYPE=FUNCTION" and FILTER at the same time. Also, FORCE\_NOT\_NULL in CSV option cannot be used with FILTER option.

`CHECK_CONSTRAINTS = YES | NO`

Specify whether CHECK constraints are checked during the loading. The default is NO. You must not specify both "WRITER=BINARY" and CHECK\_CONSTRAINTS at the same time.

`PARSE_ERRORS = n`

The number of ingored tuples that throw errors during parsing, encoding checks, encoding conversion, FILTER function, CHECK constraint checks, NOT NULL checks, or data type conversion. Invalid input tuples are not loaded and recorded in the PARSE BADFILE. The default is 0. If there are equal or more parse errors than the value, already loaded data is committed and the remaining tuples are not loaded. 0 means to allow no errors, and -1 and INFINITE mean to ignore all errors.

`DUPLICATE_ERRORS = n`

The number of ingored tuples that violate unique constraints. Conflicted tuples are removed from the table and recorded in the DUPLICATE BADFILE. The default is 0. If there are equal or more unique violations than the value, the whole load is rolled back. 0 means to allow no violations, and -1 and INFINITE mean to ignore all violations. You must not specify both "WRITER=BINARY" and DUPLICATE\_ERRORS at the same time.

`ON_DUPLICATE_KEEP = NEW | OLD`

Specify how to handle tuples that violate unique constraints. The removed tuples are recorded in the BAD file. The default is NEW. You also need to set DUPLICATE\_ERRORS to more than 0 if you enable the option. You must not specify both "WRITER=BINARY" and ON\_DUPLICATE\_KEEP at the same time.

- NEW : Keep tuples in the input data, and remove corresponding existing tuples. When both violated tuples are in the data, keep the latter one.
- OLD : Keep existing tuples and remove tuples in the input data.

`LOGFILE = path`

A path to write the result log. If specified by a relative path, it is treated as same as INPUT. The default is \$LTDATA/lt\_bulkload/timestamp\_dbname\_schema\_table.log.

`PARSE_BADFILE = path`

A path to the BAD file logging invalid records which caused an error during parsing, encoding checks, encoding conversion, FILTER function, CHECK constraint checks, NOT NULL checks, or data type conversion. The format of the file is same as the input source file. If specified by a relative path, it is treated as same as INPUT. The default is \$LTDATA/lt\_bulkload/timestamp\_dbname\_schema\_table.bad.extension-of-infile.

`DUPLICATE_BADFILE = path`

A path to write bad records that conflict with unique constraints during index rebuild. The format of the file is always CSV. If specified by a relative path, it is treated as same as INPUT. The default is \$LTDATA/lt\_bulkload/timestamp\_dbname\_schema\_table.dup.csv. You must not specify both "WRITER=BINARY" and DUPLICATE\_BADFILE at the same time.

TRUNCATE = YES | NO

If YES, delete all rows from the target table with TRUNCATE command. If NO, do nothing. The default is NO. You must not specify both "WRITER=BINARY" and TRUNCATE at the same time.

VERBOSE = YES | NO

If YES, write bad tuples also in server log. If NO, don't write them in serverlog. The default is NO.

MULTI\_PROCESS = YES | NO

If YES, we do data reading, parsing and writing in parallel by using multiple threads. If NO, we use only single thread for them instead of doing parallel processing. The default is NO. If WRITER is PARALLEL, MULTI\_PROCESS is ignored. If password authentication is configured to the database to load, you have to set up the password file. See Restrictions for details. Please make sure when enabling MULTI\_PROCESS that no other LightDB backend process is trying to modify the schema of the table, because it may cause the schema of the table as seen by the reader and the writer processes to differ and cause problems.

### F.22.5.2. CSV input format

DELIMITER = delimiter\_character

The single ASCII character that separates columns within each row (line) of the file. The default is comma. When you load a tab-separated format file (TSV), you can set DELIMITER to a tab character. Then, you need to double quote the tab:

```
DELIMITER=" " # a double-quoted tab
```

You can also specify DELIMITER as a command-line -o option with '\$\t' syntax.

```
$ lt_bulkload tsv.ct1 -o '$\t'
```

QUOTE = quote\_character

Specifies the ASCII quotation character. The default is double-quotation.

ESCAPE = escape\_character

Specifies the ASCII character that should appear before a QUOTE data character value. The default is double-quotation.

NULL = null\_string

The string that represents a null value. The default is a empty value with no quotes.

FORCE\_NOT\_NULL = column

Process each specified column as though it were not a NULL value. Multiple columns are available as needed. FILTER cannot be used together with this option.

### F.22.5.3. Binary input format

COL = type [ (size) ] [ NULLIF { 'null\_string' | null\_hex } ]

Column definitions of input file from left to right. The definitions consists of type name, offset, and length in bytes. CHAR and VARCHAR means input data is a text. Otherwise, it is a binary data. If binary, endian must match between server and data file.

- CHAR | CHARACTER : a string trimmed trailing spaces. The length is always required.
- VARCHAR | CHARACTER VARYING : a string keeping trailing spaces. The length is always required.
- SMALLINT | SHOFT : signed integer in 2 bytes.
- INTEGER | INT : signed integer in 2 or 4 or 8 bytes. The default is 4.
- BIGINT | LONG : signed integer in 8 bytes.
- UNSIGNED SMALLINT | SHORT : unsigned integer in 2 bytes.
- UNSIGNED INTEGER | INT : unsigned integer in 2 or 4 bytes. The default is 4.
- FLOAT | REAL : floating point number in 4 or 8 bytes. The default is 4.
- DOUBLE : floating point number in 8 bytes.

The length and offset of the type can be specified as follows:

- TYPE : TYPE with default length follows.
- TYPE(L) : TYPE with L bytes follows.
- TYPE(S+L) : L bytes, offset S bytes from the beginning of the line
- TYPE(S:E) : start at S bytes and end at E bytes.

The length and offset of the type can be specified as follows:

- NULLIF 'null\_string' : Specify the string expressing NULL when the type is CHAR or VARCHAR. The length of the string must be the same as that of the type.
- NULLIF null\_hex : Specify the hex value expressing NULL when the type is other than CHAR and VARCHAR. The length of the hex value must be the same as that of the type.

In addition, "COL N" is available, that is same as COL CHAR(N), for backward compatibility.

PRESERVE\_BLANKS = YES | NO

YES regards following "COL N" as "COL CHAR(N)" and NO as "COL VARCHAR(N)". Default is NO.

STRIDE = n

Length of one row. Use if you want to truncate the end of row. The default is whole of the row, which means the total of COLs.

#### F.22.5.4. Binary output format

OUT\_COL = type [ (size) ] [ NULLIF { 'null\_string' | null\_hex } ]

Column definitions of output file from left to right. The definitions consists of type name, offset, and length in bytes. CHAR and VARCHAR means input data is a text. Otherwise, it is a binary data. If binary, endian must match between server and data file.

- CHAR | CHARACTER : fixed-length string. The length must be specified. If the string to be stored is shorter than the declared length, values will be space-padded. "COL=CHAR(size)" will be output in the sample of control file.
- VARCHAR | CHARACTER VARYING : fixed-length string. The length must be specified. If the string to be stored is shorter than the declared length, values will be space-padded. "COL=VARCHAR(size)" will be output in the sample of control file.

- SMALLINT | SHOFT : signed integer in 2 bytes.
- INTEGER | INT : signed integer in 2 or 4 or 8 bytes. The default is 4.
- BIGINT | LONG : signed integer in 8 bytes.
- UNSIGNED SMALLINT | SHORT : unsigned integer in 2 bytes.
- UNSIGNED INTEGER | INT : unsigned integer in 2 or 4 bytes. The default is 4.
- FLOAT | REAL : floating point number in 4 or 8 bytes. The default is 4.
- DOUBLE : floating point number in 8 bytes.

The string expressing NULL can be specified as follows. If omitted but NULL is input, NULL is logged as an invalid data in PARSE\_BADFILE.

- NULLIF 'null\_string' : Specify the string expressing NULL when the type is CHAR or VARCHAR. The length of the string must be the same as that of the type.
- NULLIF null\_hex : Specify the hex value expressing NULL when the type is other than CHAR and VARCHAR. The length of the hex value must be the same as that of the type.

## F.22.6. Restrictions

### F.22.6.1. Exit code of lt\_bulkload

lt\_bulkload returns 0 when successfully loaded. It also returns 3 with a WARNING message when there are some parse errors or duplicate errors even if loading itself was finished. Note that skipped rows and replaced rows (with ON\_DUPLICATE\_KEEP = NEW) are not considered as an error; the exit code will be 0.

When there is a non-continuable error, the loader raises an ERROR message. The return code will be often 1 because many errors occur in the database server during loading data. The following table shows the codes that lt\_bulkload can return.

	Return code	Description
	0	Success
in LightDB	1	Error occurred during running SQL
	2	Failed to connect to LightDB
be loaded	3	Success, but some data could not

### F.22.6.2. On direct loading

If you use direct load mode (WRITER=DIRECT or PARALLEL), you have to be aware below:

#### F.22.6.2.1. LightDB startup sequence

When lt\_bulkload is crashed and some .loadstatus files are remained in \$LTDATA/lt\_bulkload, database must be recovered by lt\_bulkload own recovery with "lt\_bulkload -r" command before you invoke lt\_ctl start. You must start and stop LightDB using LightDB script, which invokes "lt\_bulkload -r" and "lt\_ctl start" correctly. We recommend not to use lt\_ctl directly.

If you use lt\_bulkload in Windows operating system, LightDB script is not included in a lt\_bulkload package. So you have to invoke "lt\_bulkload -r" manually.

### F.22.6.2.2. PITR/Replication

Because of bypassing WAL, archive recovery by PITR is not available. This does not mean that it can be done PITR without loaded tables data. If you would like to use PITR, take a full backup of the database after load via `lt_bulkload`. If you are using streaming replication, you need to re-create your standby based on the backup set which is taken after `lt_bulkload`.

### F.22.6.2.3. Load status file in `$LTDATA/lt_bulkload`

You must not remove the load status file (`*.loadstatus`) found in `$LTDATA/lt_bulkload` directory. This file is needed in `lt_bulkload` crash recovery.

### F.22.6.2.4. Do not use `kill -9`

Do not terminate `lt_bulkload` command using `"kill -9"` as much as possible. If you did this, you must invoke LightDB script to perform `lt_bulkload` recovery and restart LightDB to continue.

### F.22.6.2.5. Authentication can fail when `MULTI_PROCESS=YES`

When `MULTI_PROCESS=YES` and password is required to connect from localhost to the database to load, the authentication will fail even if you enter the password correctly in the prompt. To avoid this, configure either of the followings.

- Use "trust" method to authenticate the connection from localhost

In UNIX environment, the connection from localhost uses UNIX-domain socket, and in Windows, it uses TCP/IP loopback address. In UNIX, add the following line into `lt_hba.conf`.

```

                                # TYPE  DATABASE          USER
CIDR-ADDRESS                   METHOD [for UNIX]
                                local   all                foo
                                trust

```

In Windows, add the following line into `lt_hba.conf`.

```

                                # TYPE  DATABASE          USER
CIDR-ADDRESS                   METHOD [for Windows]
                                host    all                foo
127.0.0.1/32                   trust

```

- Specify the password in `.pgpass` file

If you don't want to use "trust" method for security reasons, use "md5" or "password" as an authentication method and specify the password in `.pgpass` file. Note that the `.pgpass` file must be in the home directory of the OS user (typically "LightDB" user) who ran LightDB server. For example, if `lt_bulkload` connects to the server that is running on port 5432 as the DB user "foo" whose password is "foopass", the administrator can add the following line to the `.pgpass` file:

```
localhost:5432:*:foo:foopass
```

- Specify the password in `.pgpass` file

Don't use `"WRITER=PARALLE"`

Use the loading method other than  
"WRITER=PARALLEL".

### F.22.6.3. Database Constraints

Only unique constraint and not-NULL constraint are enforced during data load in default. You can to set "CHECK\_CONSTRAINTS=YES" to check CHECK constraints. Foreign key constraints cannot be checked. It is user's responsibility to provide valid data set.

## F.22.7. Details

### F.22.7.1. How to write FILTER functions

There are some notes and warnings when you write FILTER functions:

- Records in the input file are passed to the FILTER function one-by-one.
- When an error occurs in the FILTER function, the passed record is not loaded and written into PARSE BADFILE.
- The FILTER function must return record type or some composite type. Also, the actual record type must match with the target table definition.
- If the FILTER function returns NULL, a record that has NULLs in all columns is loaded.
- Functions with default arguments are supported. If the input data has fewer columns than arguments of the function, default values will be used.
- VARIADIC functions are NOT supported.
- SETOF funtions are NOT supported.
- Functions that have generic types (any, anyelement etc.) are NOT supported.
- FILTER functions can be implemented with any languages. SQL, C, PLs are ok, but you should write functions as fast as possible because they are called many times.
- You can only specify one of FILTER or FORCE\_NOT\_NULL options. Please re-implement FORCE\_NOT\_NULL-compatible FILTER functions if you need the feature.

Here is an example of FILTER function.

```
CREATE FUNCTION sample_filter(integer, text, text,  
real DEFAULT 0.05) RETURNS record  
AS $$ SELECT $1 * $4, upper($3) $$  
LANGUAGE SQL;
```

## F.23. It\_cheat\_funcs

This extension provides cheat (but useful) functions on LightDB.

### F.23.1. Functions

Note that **CREATE EXTENSION It\_cheat\_funcs** needs to be executed in all the databases that you want to execute the functions that this extension provides.

```
=# CREATE EXTENSION lt_cheat_funcs;
```

### F.23.1.1. SETOF record pg\_stat\_get\_memory\_context()

Return statistics about all memory contexts. This function returns a record, shown in the table below.

Column Name	Data Type	Description
name	text	context name
parent	text	name of parent context
level	integer	distance from TopMemoryContext in context tree
total_bytes	bigint	total bytes requested from malloc
total_nblocks	bigint	total number of malloc blocks
free_bytes	bigint	free space in bytes
free_chunks	bigint	number of free chunks
used_bytes	bigint	used space in bytes

This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

### F.23.1.2. void pg\_stat\_print\_memory\_context()

Cause statistics about all memory contexts to be logged. The format of log message for each memory context is:

```
[name]: [total_bytes] total in [total_nblocks] blocks; [free_bytes]
free ([free_chunks] chunks); [used_bytes] used
```

For descriptions of the above fields, please see pg\_stat\_get\_memory\_context().

This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

### F.23.1.3. record pg\_cached\_plan\_source(stmt text)

Return information about cached plan source of the specified prepared statement. This function returns a record, shown in the table below.

Column Name	Data Type	Description
generic_cost	double precision	cost of generic plan, or -1 if not known
total_custom_cost	double precision	total cost of custom plans so far
num_custom_plans	integer	number of plans included in total
force_generic	boolean	force use of generic plan?
force_custom	boolean	force use of custom plan?

### F.23.1.4. void pg\_signal\_process(pid int, signame text)

Send a signal to LightDB server process. This function can signal to only postmaster, backend, walsender and walreceiver process. Valid signal names are HUP, INT, QUIT, ABRT, KILL, TERM, USR1, USR2, CONT, and STOP. This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

For example, terminate walreceiver process:

```
=# SELECT pg_signal_process(pid, 'TERM') FROM pg_stat_wal_receiver;
```

### F.23.1.5. integer `pg_get_priority(pid int)`

Return the scheduling priority (“nice”) of the specified LightDB server process. This function can get the priority of only postmaster, backend, walsender and walreceiver process. See `getpriority(2)` man page for details about a scheduling priority. This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

### F.23.1.6. void `pg_set_priority(pid int, priority int)`

Set the scheduling priority (“nice”) of the specified LightDB server process to the specified value. This function can change the priority of only postmaster, backend, walsender and walreceiver process. See `getpriority(2)` man page for details about a scheduling priority. This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

### F.23.1.7. void `pg_segmentation_fault(treat_fatal_as_error boolean)`

Cause segmentation fault. If `lt_cheat_funcs.exit_on_segv` is enabled and `treat_fatal_as_error` is true, segmentation fault that this function causes will lead to ERROR instead of FATAL error. This is intended mainly for testing. This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

### F.23.1.8. void `pg_process_config_file()`

Read and process the configuration file. Note that, if an error occurs, it’s logged with DEBUG2 level. This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

### F.23.1.9. text `pg_xlogfile_name(location pg_lsn, recovery boolean)`

Convert transaction log location string to file name. This function is almost the same as `pg_xlogfile_name()` which LightDB core provides. The difference of them is whether there is a second parameter of type boolean. If false, this function always fails with an error during recovery. This is the same behavior as the core version of `pg_xlogfile_name()`. If true, this function can be executed even during recovery. But note that the first 8 digits of returned WAL filename (which represents the timeline ID) can be completely incorrect. That is, this function can return bogus WAL file name. For details of this conversion, please see Section 9.27.3.

### F.23.1.10. SETOF record `pg_stat_get_syncprep_waiters()`

Return statistics about all server processes waiting for synchronous replication. This function returns a record per server process waiting for synchronous replication, shown in the table below.

Column Name	Data Type	Description
pid	integer	Process ID of a server process
wait_lsn	pg_lsn	Transaction log position to wait for
wait_mode	text	Wait mode of this server process

Possible values of `wait_mode` are `write`, `flush` and `apply`.

This function is restricted to superusers by default, but other users can be granted `EXECUTE` to run the function.

### F.23.1.11. `void pg_wait_syncrep(location pg_lsn)`

Wait for synchronous replication. This function waits until the given transaction log location is acknowledged by synchronous standbys, based on the setting of `synchronous_commit`.

This function is restricted to superusers by default, but other users can be granted `EXECUTE` to run the function.

### F.23.1.12. `xid pg_set_next_xid(transactionid xid)`

Set and return the next transaction ID. Note that this function doesn't check if it's safe to assign the given transaction ID to the next one. The caller must carefully choose the safe transaction ID, e.g., which doesn't cause a transaction ID wraparound problem. This function is restricted to superusers by default, but other users can be granted `EXECUTE` to run the function.

### F.23.1.13. SETOF record `pg_xid_assignment()`

Return information about transaction ID assignment state. This function returns a record, shown in the table below.

Column Name	Data Type	Description
<code>next_xid</code>	<code>xid</code>	next transaction ID to assign
<code>oldest_xid</code>	<code>xid</code>	cluster-wide minimum <code>datfrozenxid</code>
<code>xid_vac_limit</code>	<code>xid</code>	start forcing autovacuum here
<code>xid_warn_limit</code>	<code>xid</code>	start complaining here
<code>xid_stop_limit</code>	<code>xid</code>	refuse to advance next transaction ID beyond here
<code>xid_wrap_limit</code>	<code>xid</code>	where the world ends
<code>oldest_xid_db</code>	<code>oid</code>	database with minimum <code>datfrozenxid</code>

This function is restricted to superusers by default, but other users can be granted `EXECUTE` to run the function.

### F.23.1.14. `xid pg_set_next_oid(objectid oid)`

Set and return the next object ID (OID). Note that the next OID is set to 16384 (`FirstNormalObjectId`) when the given OID is less than that number. This function is restricted to superusers by default, but other users can be granted `EXECUTE` to run the function.

### F.23.1.15. SETOF record `pg_oid_assignment()`

Return information about object ID (OID) assignment state. This function returns a record, shown in the table below.

Column Name	Data Type	Description
<code>next_oid</code>	<code>oid</code>	next object ID to assign
<code>oid_count</code>	<code>integer</code>	OIDs available before must do WAL work

This function is restricted to superusers by default, but other users can be granted `EXECUTE` to run the function.

### F.23.1.16. integer `pg_advance_vacuum_cleanup_age(integer)`

Specify the number of transactions by which VACUUM and HOT updates will advance cleanup of dead row versions. `vacuum_defer_cleanup_age` in the session calling this function is set to the negative value of that specified number. If the argument is omitted or NULL is specified, `vacuum_defer_cleanup_age` is reset to its original setting value specified in the configuration file. This function returns the vacuum cleanup age.

By advancing the cleanup age, VACUUM and HOT updates can clean up even dead tuples that were produced since oldest transaction had started. So this function is helpful to prevent the database from bloating due to unremovable dead tuples while long transaction is running.

Note that this is extremely dangerous function and can easily corrupt the database. Any important data may disappear and data consistency may be lost completely. This function must not be used for a purpose other than debug.

This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

### F.23.1.17. void `pg_checkpoint(fast bool, wait bool, force bool)`

Perform a checkpoint. If `fast` is true (default), a checkpoint will finish as soon as possible. Otherwise, I/O required for a checkpoint will be spread out over a period of time, to minimize the impact on query processing. If `wait` is true (default), this function waits for a checkpoint to complete before returning. Otherwise, it just signals checkpointer to do it and returns. If `force` is true (default), this function forces a checkpoint even if no WAL activity has occurred since the last one. This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

### F.23.1.18. SETOF record `pg_recovery_settings()`

Return information about all parameter settings in `recovery.conf`. This function returns a record, shown in the table below.

Column Name	Data Type	Description
<code>name</code>	text	configuration parameter name
<code>setting</code>	text	value of the parameter

This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

### F.23.1.19. text `pg_show_primary_conninfo()`

Return the current value of `primary_conninfo` recovery parameter. If it's not set yet, NULL is returned. This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function. For details of `primary_conninfo` parameter, please see `primary_conninfo`.

### F.23.1.20. integer `pg_postmaster_pid()`

Return the Process ID of the postmaster process.

### F.23.1.21. timestamp with time zone `pg_backend_start_time()`

Return the time when the server process attached to the current session was started.

### F.23.1.22. SETOF text `pg_list_relation_filepath(relation regclass)`

List the file path names of the specified relation.

**F.23.1.23. text pg\_tablespace\_version\_dirctry()**

Return the name of major-version-specific tablespace subdirectory.

**F.23.1.24. bigint pg\_file\_write\_binary(filepath text, data bytea)**

Write bytea data to the file. This function creates the file if it does not exist, and truncates it to zero length otherwise. Then this function writes the bytea data from the beginning of the file, and returns the number of bytes written. This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

**F.23.1.25. void pg\_file\_fsync(filepath text)**

Try to fsync the file or directory. This function is restricted to superusers by default, but other users can be granted EXECUTE to run the function.

**F.23.1.26. text to\_octal(integer or bigint)**

Convert number to its equivalent octal representation.

**F.23.1.27. text pg\_text\_to\_hex(str text)**

Convert text to its equivalent hexadecimal representation.

Here is an example of the conversion from text to hex:

```
=# SELECT pg_text_to_hex('LightDB');
   pg_text_to_hex
-----
4c696768744442
(1 row)
```

**F.23.1.28. text pg\_hex\_to\_text(hex text)**

Convert hexadecimal representation to its equivalent text.

Here is an example of the conversion from hex to text:

```
=# SELECT pg_hex_to_text('4c696768744442');
   pg_hex_to_text
-----
LightDB
(1 row)
```

**F.23.1.29. text pg\_chr(code integer)**

Return the character with the given code. This function is almost the same as chr() which LightDB core provides. The difference of them is that this function returns NULL instead of throwing an error when the requested character is too large or not valid. Note that valid Unicode code point stops at U+10FFFF (1114111), even though 4-byte UTF8 sequences can hold values up to U+1FFFFFF. Therefore this function returns NULL whenever the given code is larger than 1114111.

**F.23.1.30. text pg\_utf8(code integer)**

Alias of pg\_chr(code integer). function.

### F.23.1.31. SETOF record pg\_all\_utf8()

Return all valid UTF-8 characters. This function returns a record, shown in the table below.

Column Name	Data Type	Description
code	text	code of character
utf8	text	UTF-8 character

This function can be executed only under UTF-8 database encoding.

### F.23.1.32. text pg\_eucjp(code1 bit(8), code2 bit(8), code3 bit(8))

Return EUC\_JP character with the given codes. The following table shows the valid combination of the codes.

code1	code2	code3
x00 - x7f	-	-
x8e	xa1 - xdf	-
xa1 - xfe	xa1 - xfe	-
x8f	xa1 - xfe	xa1 - xfe

For example, return EUC\_JP character with “a1fa” (BLACK STAR):

```
=# SELECT pg_eucjp('xa1', 'xfa');
```

This function returns NULL when the requested character is invalid for EUC\_JP. This function can be executed only under EUC\_JP database encoding.

### F.23.1.33. SETOF record pg\_all\_eucjp()

Return all valid EUC\_JP characters. This function returns a record, shown in the table below.

Column Name	Data Type	Description
code1	text	first byte of character
code2	text	second byte of character (x00 means non-existence of this byte)
code3	text	third byte of character (x00 means non-existence of this byte)
eucjp	text	EUC_JP character

This function can be executed only under EUC\_JP database encoding.

### F.23.1.34. bytea pglz\_compress(data text)

Create and return a compressed version of text data. This function uses PGLZ (an implementation of LZ compression for LightDB) for the compression. If the compression fails (e.g., the compressed result is actually bigger than the original), this function returns the original data. Note that the return data may be 4-bytes bigger than the original even when the compression fails because 4-bytes extra information like the length of original data is always stored in it. The bytea data that this function returns needs to be decompressed by using pg\_lz\_decompress() to obtain the original text data.

### F.23.1.35. bytea pglz\_compress\_bytea(data bytea)

Create and return a compressed version of bytea data. This function uses PGLZ (an implementation of LZ compression for LightDB) for the compression. If the compression fails (e.g., the compressed

result is actually bigger than the original), this function returns the original data. Note that the return data may be 4-bytes bigger than the original even when the compression fails because 4-bytes extra information like the length of original data is always stored in it. The bytea data that this function returns needs to be decompressed by using `pg_lz_decompress_bytea()` to obtain the original bytea data.

### **F.23.1.36. text `pglz_decompress(data bytea)`**

Decompress a compressed version of bytea data into text. Note that the input of this function must be the bytea data that `pg_lz_compress()` or `pg_lz_compress_bytea()` returned. Otherwise this function may return a corrupted data.

### **F.23.1.37. bytea `pglz_decompress_bytea(data bytea)`**

Decompress a compressed version of bytea data into bytea. Note that the input of this function must be the bytea data that `pg_lz_compress()` or `pg_lz_compress_bytea()` returned. Otherwise this function may return a corrupted data.

### **F.23.1.38. text `pg_saslprep(input text)`**

Normalize an input string with SASLprep. SASLprep normalization is basically used to process a user-supplied password into canonical form for SCRAM authentication. Note that an error is raised if the input is not a valid UTF-8 string or the normalized string contains characters prohibited by the SASLprep profile.

### **F.23.1.39. `pg_advisory_xact_unlock(bigint)`**

Release a previously-acquired exclusive transaction-level advisory lock. Return true if the lock is successfully released. If the lock was not held, false is returned, and in addition, an SQL warning will be reported by the server.

### **F.23.1.40. `pg_advisory_xact_unlock_shared(bigint)`**

Release a previously-acquired shared transaction-level advisory lock. Return true if the lock is successfully released. If the lock was not held, false is returned, and in addition, an SQL warning will be reported by the server.

### **F.23.1.41. `pg_advisory_xact_unlock(integer, integer)`**

Same as `pg_advisory_xact_unlock(bigint)`.

### **F.23.1.42. `pg_advisory_xact_unlock_shared(integer, integer)`**

Same as `pg_advisory_xact_unlock_shared(bigint)`.

## **F.23.2. Encoding Conversions**

### **F.23.2.1. `pg_euc_jp_to_utf8`**

This is an encoding conversion from EUC\_JP to UTF-8. It uses two conversion maps; ordinary map and extra map. They are defined in `conv/euc_jp_to_utf8.map` and `conv/euc_jp_to_utf8.extra`, respectively. For each character, ordinary map is consulted first. If no match is found, extra map is consulted next. If still no match, an error is raised.

The content of ordinary map is the same as the map that `euc_jp_to_utf8` (default conversion map from EUC\_JP to UTF-8 that LightDB provides) uses. The extra map contains some mappings (e.g., the following mappings for Roman numerals and full-width symbols) that ordinary map doesn't have.

EUC_JP	UTF-8	Description
fcf1	e285b0 (U+2170)	SMALL ROMAN NUMERAL ONE
fcf2	e285b1 (U+2171)	SMALL ROMAN NUMERAL TWO
fcf3	e285b2 (U+2172)	SMALL ROMAN NUMERAL THREE
fcf4	e285b3 (U+2173)	SMALL ROMAN NUMERAL FOUR
fcf5	e285b4 (U+2174)	SMALL ROMAN NUMERAL FIVE
fcf6	e285b5 (U+2175)	SMALL ROMAN NUMERAL SIX
fcf7	e285b6 (U+2176)	SMALL ROMAN NUMERAL SEVEN
fcf8	e285b7 (U+2177)	SMALL ROMAN NUMERAL EIGHT
fcf9	e285b8 (U+2178)	SMALL ROMAN NUMERAL NINE
fcfa	e285b9 (U+2179)	SMALL ROMAN NUMERAL TEN
fcfb	efbfa2 (U+FFE2)	FULLWIDTH NOT SIGN
fcfc	efbfa4 (U+FFE4)	FULLWIDTH BROKEN BAR
fcfd	efbc87 (U+FF07)	FULLWIDTH APOSTROPHE
fcfe	efbc82 (U+FF02)	FULLWIDTH QUOTATION MARK

In order to use `pg_euc_jp_to_utf8` as the default conversion from EUC\_JP to UTF-8, its `pg_conversion.condefault` needs to be enabled. Also `condefault` for `euc_jp_to_utf8` (built-in conversion from EUC\_JP to UTF-8) needs to be disabled. Here is an example of these catalog updates:

```

=# BEGIN;
=# UPDATE pg_conversion SET condefault = 'f' WHERE conname =
  'euc_jp_to_utf8';
=# UPDATE pg_conversion SET condefault = 't' WHERE conname =
  'pg_euc_jp_to_utf8';
=# COMMIT;

```

It's possible to use the customized conversion map by modifying the map files directly and rebuilding `lt_cheap_funcs` module. Note that entries in a map file must be sorted in ascending order.

## F.23.3. Configuration Parameters

Note that `shared_preload_libraries` or `session_preload_libraries` must be set to `"lt_cheap_funcs"` in `lightdb.conf` if you want to use the configuration parameters which this extension provides.

### F.23.3.1. `lt_cheap_funcs.log_memory_context` (boolean)

Cause statistics about the memory contexts to be logged at the end of query execution. For details of log format, please see `pg_stat_print_memory_context()`. This parameter is off by default. Only superusers can change this setting.

### F.23.3.2. `lt_cheap_funcs.hide_appname` (boolean)

If true, client's `application_name` is ignored and its setting value is stored in `lt_cheap_funcs.hidden_appname` parameter. By default, this is set to false, so that the string that client specifies will be used as `application_name`. This parameter can only be set in the `lightdb.conf` file or on the server command line.

### F.23.3.3. `lt_cheap_funcs.hidden_appname` (string)

Report client's `application_name` hidden from view. The default is an empty string. Any users can change this setting.

### F.23.3.4. `lt_cheap_funcs.log_session_start_options` (boolean)

Log options sent to the server at connection start. This parameter is off by default. Only superusers can change this parameter at session start, and it cannot be changed at all within a session.

### F.23.3.5. `lt_cheap_funcs.scheduling_priority` (integer)

Specify the scheduling priority ("nice") of LightDB server process. Valid values are between -20 and 19. Lower values cause more favorable scheduling. The default value is zero. Any users can change this setting. See `getpriority(2)` man page for details about a scheduling priority.

### F.23.3.6. `lt_cheap_funcs.exit_on_segv` (boolean)

If off, which is the default, segmentation fault will lead to the server crash. If on, only the current session causing segmentation fault will be terminated. Any users can change this setting.

## F.24. `ltcluster`

See `ltcluster`<sup>1</sup> for more details.

## F.25. `ltcron`

### F.25.1. What is `ltcron`?

`ltcron` is a simple cron-based job scheduler for LightDB that runs inside the database as an extension. It allows you to schedule LightDB commands directly from the database:

```
-- Vacuum on Saturday at 3:30am (East eight time zone)
SELECT cron.schedule('30 3 * * 6', 'VACUUM');
schedule
-----
42

-- Vacuum every day at 10:00am (East eight time zone)
SELECT cron.schedule('nightly-vacuum', '0 10 * * *',
'VACUUM');
schedule
-----
43
```

---

<sup>1</sup> <http://www.light-pg.com/docs/ltcluster/13.8-23.4/index.html>

```

-- Change to vacuum at 3:00am (East eight time zone)
SELECT cron.schedule('nightly-vacuum', '0 3 * * *',
'VACUUM');
  schedule
  -----
         43

-- Stop scheduling jobs
SELECT cron.unschedule('nightly-vacuum' );
  unschedule
  -----
  t
(1 row)

SELECT cron.unschedule(42);
  unschedule
  -----
  t

```

It\_cron can support second-level precision:

```

zone)
-- Vacuum every day at 10:00:30am (East eight time
SELECT cron.schedule('30 0 10 * * *', 'VACUUM');
  schedule
  -----
         45

-- Vacuum every second
SELECT cron.schedule('dayly-vacuum', '* * * * *',
'VACUUM');
  schedule
  -----
         46

-- Change to Vacuum every 10 seconds
SELECT cron.schedule('dayly-vacuum', '*/10 * * * * *',
'VACUUM');
  schedule
  -----
         46

```

It\_cron can support four task modes, include one-time tasks, asap takes, next interval tasks and fixed interval tasks. You can pass in the task mode in the fourth parameter and there are four parameters to choose from (If you want to configure the task mode, the first parameter task name must be passed in):

- 'single' represents a one-time task, this means that when the task is executed for the first time, the task will not be executed again.

```

-- Change to Vacuum only once immediately
SELECT cron.schedule('dayly-vacuum', '* * * * *',
'VACUUM', 'single');
  schedule
  -----
         46

```

```

-- Change to Vacuum every 30 seconds
SELECT cron.schedule('daily-vacuum', '* / 30 * * * * *',
'VACUUM', 'next');
    schedule
    -----
        46

```

```

-- Change to Vacuum only once at the next 10:00:30am
(East eight time zone)
SELECT cron.schedule('daily-vacuum', '30 0 10 * * *',
'VACUUM', 'single');
    schedule
    -----
        46

```

```

-- Change to Vacuum every day at 10:00:30am (East eight
time zone)
SELECT cron.schedule('daily-vacuum', '30 0 10 * * *',
'VACUUM', 'next');
    schedule
    -----
        46

```

- 'asap' represents a asap scheduled task, for the same task it runs at most one instance of a job at a time. If a second run is supposed to start before the first one finishes, then the second run is queued and started as soon as the first run completes.

```

-- Change to Vacuum every 30 seconds
SELECT cron.schedule('daily-vacuum', '* / 30 * * * * *',
'VACUUM', 'asap');
    schedule
    -----
        46

```

```

-- Change to Vacuum every day at 10:00:30am (East eight
time zone)
SELECT cron.schedule('daily-vacuum', '30 0 10 * * *',
'VACUUM', 'asap');
    schedule
    -----
        46

```

- 'next' represents a next interval scheduled task, for the same task it runs at most one instance of a job at a time. If a second run is supposed to start before the first one finishes, then the second run is queued and started at the time point of the next timing cycle.

Compatible with the previous version, the mode parameter input 'timing' is the same as 'next'.

```

-- Change to Vacuum every 30 seconds
SELECT cron.schedule('daily-vacuum', '* / 30 * * * * *',
'VACUUM', 'next');
    schedule
    -----

```

46

```

-- Change to Vacuum every day at 10:00:30am (East eight
time zone)
SELECT cron.schedule('daily-vacuum', '30 0 10 * * *',
'VACUUM', 'next');

```

```

schedule
-----

```

46

- 'fixed' represents a fixed interval scheduled task, for the same task it runs at most four instances of a job at a time by default. If a second run is supposed to start before the first one finishes, then the second run will not wait, and will start at the time point of the timing cycle, then will be executed in parallel with the first unfinished task.

You can modify the maximum number of concurrent executions for the same task when it expires by configuring the 'cron.max\_connections\_per\_task' GUC parameters in the lightdb.conf and restarting the database to take effect. The maximum upper limit is 16.

```

-- Change to Vacuum every 30 seconds
SELECT cron.schedule('daily-vacuum', '*/30 * * * * *',
'VACUUM', 'fixed');

```

```

schedule
-----

```

46

```

-- Change to Vacuum every day at 10:00:30am (East eight
time zone)
SELECT cron.schedule('daily-vacuum', '30 0 10 * * *',
'VACUUM', 'fixed');

```

```

schedule
-----

```

46

It\_cron can support time zone configuration. You can pass the timezone value in the fifth parameter. If you want to configure the time zone, the first parameter task name and the fourth parameter task mode must be passed in. If no time zone is configured, the default is East eight time zone:

```

-- Change to Vacuum every day at 10:00am (GMT)
SELECT cron.schedule('daily-vacuum', '0 10 * * *',
'VACUUM', 'next', '0');

```

```

schedule
-----

```

46

```

-- Change to vacuum every day at 10:00am (West ten time
zone)

```

```

SELECT cron.schedule('daily-vacuum', '0 10 * * *',
'VACUUM', 'next', '-10');

```

```

schedule
-----

```

46

```

-- Change to vacuum only once at the next 10:00am (East
six time zone)

```

```

SELECT cron.schedule('daily-vacuum', '0 10 * * *',
'VACUUM', 'single', '6');
schedule
-----
46

```

It\_cron can support the execution of linux os commands. You can pass the command type value in the sixth parameter. pass parameter 'sql' represents that the second parameter is the sql command, and pass parameter 'linux' represents that the second parameter is the sql command. If you want to configure the command type, the first parameter task name, the fourth parameter task mode and the fifth parameter time zone must be passed in. If no command type is configured, the default is sql command. Note that you must be a super user to execute linux commands:

```

-- Change to Vacuum every day at 10:00am (East eight
time zone)
SELECT cron.schedule('daily-vacuum', '0 10 * * *',
'VACUUM', 'next', '8', 'sql');
schedule
-----
46

-- delete log file every day at 23:59 (East eight time
zone)
SELECT cron.schedule('daily-touch', '59 23 * * *', 'rm
-rf $LTDATA/log/*', 'next', '8', 'linux');
schedule
-----
46

```

It\_cron can run multiple jobs in parallel, and by default it uses next interval mode, i.e. it runs at most one instance of a job at a time. If a second run is supposed to start before the first one finishes, then the second run is queued and started at the time point of the next timing cycle.

It\_cron supports a default timeout of 3 minutes for scheduled tasks for SQL commands, which is valid for all types of tasks. If the task execution times out, it will log the error in cron.job\_run\_details and return, waiting for the next execution. You can modify the timing task timeout time by setting the guc parameter cron.task\_running\_timeout in lightdb.conf and restarting the database to take effect. The maximum value is 60 minutes; if it is set to 0, it means there is no timeout limit.

Note that there is no timeout mechanism for linux command timing tasks.

The schedule uses the standard cron syntax, in which \* means "run every time period", and a specific number means "but only at this time":

```

##### min (0 - 59)
# ##### hour (0 - 23)
# # ##### day of month (1 - 31)
# # # ##### month (1 - 12)
# # # # ##### day of week (0 - 6) (0 to 6
are Sunday to
# # # # # Saturday, or use names; 7
is also Sunday)
# # # # #
# # # # #
* * * * *

```

An easy way to create a cron schedule is: [crontab.guru](https://crontab.guru/)<sup>2</sup>.

It has been enhanced on the basis of standard cron syntax to supports second-level tasks:

```
#####second (0 - 59)
# ##### minute (0 - 59)
# # ##### hour (0 - 23)
# # # ##### day of month (1 - 31)
# # # # ##### month (1 - 12)
# # # # # ##### day of week (0 - 6) (0 to
6 are Sunday to
# # # # # # Saturday, or use names; 7
is also Sunday)
# # # # # #
# # # # # #
* * * * *
```

For security, jobs are executed in the database in which the `cron.schedule` function is called with the same permissions as the current user. In addition, users are only able to see their own jobs in the `cron.job` table and `cron.lt_job` view.

## F.26. It\_freespacemap

The `lt_freespacemap` module provides a means for examining the free space map (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and members of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

### F.26.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN) returns int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno bigint`, `avail int2`) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

#### Note

The interface was changed in version 8.4, to reflect the new FSM implementation introduced in the same version.

<sup>2</sup> <https://crontab.guru/>

## F.26.2. Sample Output

```
lightdb@postgres=# SELECT * FROM pg_freespace('foo');
```

blkno	avail
0	0
1	0
2	0
3	32
4	704
5	704
6	704
7	1216
8	704
9	704
10	704
11	704
12	704
13	704
14	704
15	704
16	704
17	704
18	704
19	3648

```
(20 rows)
```

```
lightdb@postgres=# SELECT * FROM pg_freespace('foo', 7);  
pg_freespace
```

1216
------

```
(1 row)
```

## F.26.3. Author

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

## F.27. It\_hint\_plan

### F.27.1. Name

`It_hint_plan` -- controls execution plan with hinting phrases in comment of special form.

### F.27.2. Synopsis

LightDB uses cost based optimizer, which utilizes data statistics, not static rules. The planner (optimizer) estimates costs of each possible execution plans for a SQL statement then the execution plan with the lowest cost finally be executed. The planner does its best to select the best best execution plan, but not perfect, since it doesn't count some properties of the data, for example, correlation between columns.

`It_hint_plan` makes it possible to tweak execution plans using so-called "hints", which are simple descriptions in the SQL comment of special form.

## F.27.3. Description

### F.27.3.1. Basic Usage

lt\_hint\_plan reads hinting phrases in a comment of special form given with the target SQL statement. The special form is beginning by the character sequence "/\*+" and ends with "\*/". Hint phrases are consists of hint name and following parameters enclosed by parentheses and delimited by spaces or a comma. Each hinting phrases can be delimited by new lines for readability. the hint at the beginning of sql is called the global level hint, and the hint in the statement is called the stmt level hint(only affect current query block without using qb\_name hint).

In the example below , hash join is selected as the joining method and scanning ltbench\_accounts by sequential scan method.

```
lightdb@postgres=# /*+
lightdb@postgres*#      HashJoin(a b)
lightdb@postgres*#      SeqScan(a)
lightdb@postgres*#      */
lightdb@postgres-# EXPLAIN SELECT *
lightdb@postgres-#      FROM ltbench_branches b
lightdb@postgres-#      JOIN ltbench_accounts a ON b.bid = a.bid
lightdb@postgres-#      ORDER BY a.aid;
                                                                    QUERY PLAN
-----
          Sort  (cost=31465.84..31715.84 rows=100000 width=197)
          Sort Key: a.aid
          -> Hash Join  (cost=1.02..4016.02 rows=100000 width=197)
              Hash Cond: (a.bid = b.bid)
              -> Seq Scan on ltbench_accounts a  (cost=0.00..2640.00
              rows=100000 width=97)
              -> Hash  (cost=1.01..1.01 rows=1 width=100)
                  -> Seq Scan on ltbench_branches b
                  (cost=0.00..1.01 rows=1 width=100)
          (7 rows)

lightdb@postgres=#
```

## F.27.4. The hint table

Hints are described in a comment in a special form in the above section. This is inconvenient in the case where queries cannot be edited. In the case hints can be placed in a special table named "hint\_plan.hints". The table consists of the following columns.

**Table F.12. hint table**

column	description
id	Unique number to identify a row for a hint. This column is filled automatically by sequence.
norm_query_string	A pattern matches to the query to be hinted. Constants in the query have to be replace with '?' as in the following example. White space is significant in the pattern.
application_name	The value of application_name of sessions to apply the hint. The hint in the example below applies to sessions connected from Itsql. An empty string means sessions of any application_name.

column	description
hints	Hint phrase. This must be a series of hints excluding surrounding comment marks.

The following example shows how to operate with the hint table.

```
lightdb@postgres=# INSERT INTO hint_plan.hints(norm_query_string,
application_name, hints)
lightdb@postgres-#     VALUES (
lightdb@postgres(#     'EXPLAIN (COSTS false) SELECT * FROM t1
WHERE t1.id = ?;',
lightdb@postgres(#     '',
lightdb@postgres(#     'SeqScan(t1)'
lightdb@postgres(#     );
INSERT 0 1
lightdb@postgres=# UPDATE hint_plan.hints
lightdb@postgres-#     SET hints = 'IndexScan(t1)'
lightdb@postgres-#     WHERE id = 1;
UPDATE 1
lightdb@postgres=# DELETE FROM hint_plan.hints
lightdb@postgres-#     WHERE id = 1;
DELETE 1
lightdb@postgres=#
```

The hint table is owned by the creator user and having the default privileges at the time of creation, during CREATE EXTENSION. Table hints are prioritized than comment hints.

## F.27.4.1. The types of hints

Hinting phrases are classified into eight types based on what kind of object and how they can affect planning. Scanning methods, join methods, joining order, row number correction, parallel query, GUC setting, query block name, and other hints. You will see the lists of hint phrases of each type in Hint list.

### F.27.4.1.1. Hints for scan methods

Scan method hints enforce specific scanning method on the target table. It `hint_plan` recognizes the target table by alias names if any. They are 'SeqScan', 'IndexScan' and so on in this kind of hint.

Scan hints are effective on ordinary tables, inheritance tables, UNLOGGED tables, temporary tables and system catalogs. External(foreign) tables, table functions, VALUES clause, CTEs, views and subqueries are not affected.

```
lightdb@postgres=# /*+
lightdb@postgres*#     SeqScan(t1)
lightdb@postgres*#     IndexScan(t2 t2_pkey)
lightdb@postgres*# */
lightdb@postgres-# SELECT * FROM table1 t1 JOIN table table2 t2 ON

### F.27.4.1.2. Hints for join methods

This can affect on joins only on ordinary tables, inheritance tables, UNLOGGED tables, temporary tables, external (foreign) tables, system catalogs, table functions, VALUES command results and CTEs are allowed to be in the parameter list. But joins on views and sub query are not affected.

For oracle compatibility, keywords of 'use\_hash', 'use\_nl', 'use\_merge', 'no\_use\_hash', 'no\_use\_nl' and 'no\_use\_merge' are also supported.

When `lightdb_dblevel_syntax_compatible_type` is 'off', join method hints can specify two or more tables, and will enforce the join methods of the joins involving specified tables.

```
lightdb@postgres=# EXPLAIN (COSTS false) SELECT /*+leading(t1 t2
t3)*/ FROM t1, t2 ,t3 WHERE t1.id = t2.id and t2.id=t3.id;
LOG:  lt_hint_plan:
used hint:
Leading(((t1@lt#0 t2@lt#0) t3@lt#0))
not used hint:
duplication hint:
error hint:
```

QUERY PLAN

```
-----
Hash Join
Hash Cond: (t1.id = t3.id)
-> Hash Join
      Hash Cond: (t1.id = t2.id)
      -> Seq Scan on t1 @"lt#0"
      -> Hash
            -> Seq Scan on t2 @"lt#0"
-> Hash
      -> Seq Scan on t3 @"lt#0"
(9 rows)
```

```
lightdb@postgres=# EXPLAIN (COSTS false) SELECT /*+leading(t1 t2
t3) use_nl(t1 t2) use_merge(t1 t2 t3)*/ FROM t1, t2 ,t3 WHERE
t1.id = t2.id and t2.id=t3.id;
LOG:  lt_hint_plan:
used hint:

Merge Cond: (t1.id = t3.id)
-> Nested Loop
      -> Index Scan using t1_pkey on t1 @"lt#0"
      -> Index Scan using t2_pkey on t2 @"lt#0"
            Index Cond: (id = t1.id)
-> Index Scan using t3_pkey on t3 @"lt#0"
(7 rows)
```

```
lightdb@postgres=#
```

When `lightdb_dblevel_syntax_compatible_type` is not 'off', join method hints can specify one or more tables, and will instructs the optimizer to join each specified table with another row source using specified join method. The optimizer uses those hints when the referenced table is forced to be the inner table of a join. The hints are ignored if the referenced table is the outer table. It is recommended to be used with the join order hints('leading', 'ordered').

```
lightdb@postgres=# EXPLAIN (COSTS false) SELECT /*+leading(t1 t2
t3)*/ FROM t1, t2 ,t3 WHERE t1.id = t2.id and t2.id=t3.id;

lightdb@postgres=#

When `lightdb_dblevel_syntax_compatible_type` is not 'off', join method hints that specify more than one table can be seen as a group of join method hints that specify one table, so when there is a conflict, it only affects the tables involved. e.g: 'use\_hash(a b)' and 'use\_nl(a)' is conflicted, but for table b, use\_hash is also used.

```

lightdb@postgres=# EXPLAIN (COSTS false) SELECT /*+leading(t1 t2

### F.27.4.1.3. Hint for joining order

Normally this hint "Leading" enforces the order of join on two or more tables. There are two ways of enforcing. One is enforcing specific order of joining but not restricting direction at each join level. Another enforces join direction additionally. Details are seen in the hint list table.

```

lightdb@postgres=# /*+
lightdb@postgres*#      NestLoop(t1 t2)
lightdb@postgres*#      MergeJoin(t1 t2 t3)
lightdb@postgres*#      Leading(t1 t2 t3)
lightdb@postgres*#      */
lightdb@postgres=# SELECT * FROM table1 t1
lightdb@postgres=#      JOIN table table2 t2 ON (t1.key = t2.key)
lightdb@postgres=#      JOIN table table3 t3 ON (t2.key = t3.key);

```

For oracle compatibility, 'ordered' hint is also supported. The ORDERED hint instructs LightDB to join tables in the order in which they appear in the FROM clause. LightDB's 'ordered' hint is just an alias for 'leading' hint, so it will not override 'leading' hints like oracle does.

```
lightdb@postgres=# EXPLAIN SELECT * FROM t3, t2, t1 WHERE t1.id =
t2.id;
```

QUERY PLAN

```
-----
Nested Loop (cost=60.85..63982.64 rows=5107600 width=24)
-> Hash Join (cost=60.85..99.39 rows=2260 width=16)
    Hash Cond: (t2.id = t1.id)
        -> Seq Scan on t2 (cost=0.00..32.60 rows=2260 width=8)
        -> Hash (cost=32.60..32.60 rows=2260 width=8)
            -> Seq Scan on t1 (cost=0.00..32.60 rows=2260
width=8)

#### F.27.4.1.4. Hint for row number correction

This hint "Rows" corrects row number misestimation of joins that comes from restrictions of the planner.

This hint "Rows" also corrects row number misestimation of table or subquery.

```
lightdb@postgres=# /*+ Rows(a #10) */ SELECT... ; Sets rows of
table result to 10
lightdb@postgres=# /*+ Rows(a 10) */ SELECT... ; Sets rows of table
result to 10
lightdb@postgres=# /*+ Rows(a +10) */ SELECT... ; Increments row
number of table by 10
lightdb@postgres=# /*+ Rows(a -10) */ SELECT... ; Subtracts 10 from
the row number of table.
lightdb@postgres=# /*+ Rows(a *10) */ SELECT... ; Makes the row
number of table 10 times larger.
lightdb@postgres=# /*+ Rows(a b #10) */ SELECT... ; Sets rows of
join result to 10
lightdb@postgres=# /*+ Rows(a b 10) */ SELECT... ; Sets rows of
join result to 10
lightdb@postgres=# /*+ Rows(a b +10) */ SELECT... ; Increments row
number of join by 10
lightdb@postgres=# /*+ Rows(a b -10) */ SELECT... ; Subtracts 10
from the row number of join.
lightdb@postgres=# /*+ Rows(a b *10) */ SELECT... ; Makes the row
number of join 10 times larger.

lightdb@postgres=# /*+ cardinality(a #10) */ SELECT... ; Sets rows
of table result to 10
lightdb@postgres=# /*+ cardinality(a 10) */ SELECT... ; Sets rows
of table result to 10
lightdb@postgres=# /*+ cardinality(a +10) */ SELECT... ; Increments
row number of table by 10
lightdb@postgres=# /*+ cardinality(a -10) */ SELECT... ; Subtracts
10 from the row number of table.
lightdb@postgres=# /*+ cardinality(a *10) */ SELECT... ; Makes the
row number of table 10 times larger.
lightdb@postgres=# /*+ cardinality(a b #10) */ SELECT... ; Sets
rows of join result to 10
lightdb@postgres=# /*+ cardinality(a b 10) */ SELECT... ; Sets rows
of join result to 10
lightdb@postgres=# /*+ cardinality(a b +10) */ SELECT... ;
Increments row number of join by 10
lightdb@postgres=# /*+ cardinality(a b -10) */ SELECT... ;
Subtracts 10 from the row number of join.
lightdb@postgres=# /*+ cardinality(a b *10) */ SELECT... ; Makes
the row number of join 10 times larger.
```

For parameterized path, it is invalid, but it will affect the join cost based on parameterized path. It is different from Oracle, Oracle will not affect the join cost.

```
lightdb@postgres=# explain select /*+ use_nl(a b) leading(a b)*/
from t1 a , t2 b where a.key1=b.key1;
```

QUERY PLAN

```
-----

chuhx@postgres=#

### F.27.4.1.5. Hint for parallel plan

This hint "Parallel" enforces parallel execution configuration on scans. The third parameter specifies the strength of enforcement. "soft" means that `lt_hint_plan` only changes `max_parallel_worker_per_gather` and leave all others to planner. "hard" changes other planner parameters so as to forcibly apply the number. This can affect on ordinary tables, inheritance parents, unlogged tables and system catalogues. External tables, table functions, values clause, CTEs, views and subqueries are not affected. Internal tables of a view can be specified by its real name/alias as the target object. The following example shows that the query is enforced differently on each table.

```

lightdb@postgres=# explain /*+ Parallel(c1 3 hard) Parallel(c2 5
hard) */

```

```

        SELECT c2.a FROM c1 JOIN c2 ON (c1.a = c2.a);
        QUERY PLAN

```

```

rows=20000 width=4)

```

This hint "Parallel" can also be used by specifying just an integer, indicating that it works for all tables in the current query block.

```

lightdb@postgres=# explain select /*+parallel(3)*/ from t1, t2
where t1.id=t2.id;

```

QUERY PLAN

-----  
-----

```

Hash Join (cost=28.25..34.19 rows=2260 width=16)
Hash Cond: (t1.id = t2.id)
-> Gather (cost=0.00..0.00 rows=2260 width=8)
      Workers Planned: 3
      -> Parallel Seq Scan on t1 @"lt#0" (cost=0.00..0.00
rows=729 width=8)
-> Hash (cost=0.00..0.00 rows=2260 width=8)
      -> Gather (cost=0.00..0.00 rows=2260 width=8)
            Workers Planned: 3
            -> Parallel Seq Scan on t2 @"lt#0" (cost=0.00..0.00
rows=729 width
=8)
(9 rows)

lightdb@postgres=#

```

### F.27.4.1.6. GUC parameters temporarily setting

'Set' hint changes GUC parameters just while planning. GUC parameter shown in Query Planning can have the expected effects on planning unless any other hint conflicts with the planner method configuration parameters. GUC parameters for `lt_hint_plan` are also settable by this hint but it won't work as your expectation.

```

lightdb@postgres=# /*+ Set(random_page_cost 2.0) */
lightdb@postgres=# SELECT * FROM table1 t1 WHERE key = 'value';
...

```

'Opt\_param' hint changes GUC parameters just while planning like 'Set' hint. But there are some differences from 'Set' hint (but same with oracle):

- Parameter name should be enclosed in single quotation marks.
- Parameter values that are strings should be enclosed in single quotation marks. Numeric parameter values are specified without quotation marks.

```

EXPLAIN (COSTS false) select * from test_opt_param1 a join
test_opt_param2 b on a.key1=b.key1;
          QUERY PLAN

```

```

-----

Seq Scan on test_opt_param1 @"lt#0" (cost=0.00..38.25 rows=1
width=8)
  Filter: (key1 = 1)
(2 rows)

```

### F.27.4.1.7. Query block name

Use the `qb_name` hint to define a name for a query block. This name can then be used in another query block to hint tables appearing in the named query block. If two or more query blocks have the

same name, or if the same query block is hinted twice with different names, all the names and the hints referencing them are ignored. Query blocks that are not named using this hint have unique system-generated names.

```
lightdb@postgres=# explain select /*+indexscan(t2@qb)*/ * from t1 ,
(select /*+qb_name(qb)*/ * from t2 where id >10) as tt;
LOG:  lt_hint_plan:
used hint:

            ->  Seq Scan on t3 @qb
->  Hash
      ->  Seq Scan on t1 @"lt#0"
(8 rows)

lightdb@postgres=#

```

#### F.27.4.1.8.2. Hints for group by method(hash/sort)

The hint "use\_hash\_aggregation" instructs the optimizer to use hash aggregation when group by. The hint "no\_use\_hash\_aggregation" instructs the optimizer not to use hash aggregation when group by, then use sort.

There are two ways to use these hints. The first one has no parameters, specifying whether the current statement uses the hash algorithm, and the second one is combined with the query block name.

The following example shows the effect of the use\_hash\_aggregation hint.

```

lightdb@postgres=# EXPLAIN (COSTS false)  select max(id) from t1
where id>1 group by id order by id;
          QUERY PLAN
-----
GroupAggregate
Group Key: id
->  Index Only Scan using t1_pkey on t1
      Index Cond: (id > 1)
(4 rows)

lightdb@postgres=# EXPLAIN (COSTS false)  select /*+
use_hash_aggregation*/ max(id) from t1 where id>1 group by id
order by id;
          QUERY PLAN
-----
Sort
Sort Key: id
->  HashAggregate
      Group Key: id
      ->  Seq Scan on t1 @"lt#0"
            Filter: (id > 1)
(6 rows)

lightdb@postgres=#

```

The following example shows the effect of the no\_use\_hash\_aggregation hint.

```

lightdb@postgres=# EXPLAIN (COSTS false)  select max(id) from t1
where id>1 group by id;
          QUERY PLAN
-----
HashAggregate
Group Key: id
->  Seq Scan on t1

```

```

        Filter: (id > 1)
(4 rows)

lightdb@postgres=# EXPLAIN (COSTS false) select /*+
no_use_hash_aggregation*/ max(id) from t1 where id>1 group by id;
        QUERY PLAN
-----
GroupAggregate
Group Key: id
->  Index Only Scan using t1_pkey on t1 @"lt#0"
        Index Cond: (id > 1)
(4 rows)

lightdb@postgres=#

```

### F.27.4.1.8.3. Hints for special join(semijoin/antijoin)

Hints for semi-join are "semijoin", "hash\_sj", "nl\_sj", "merge\_sj" and "no\_semijoin", which are used to control whether to use semi-join or specify the algorithm for semi-join. Hints for anti-join are "hash\_aj", "nl\_aj", "merge\_aj", which are used to specify the algorithm for anti-join.

There are two ways to use these hints. The first one has no parameter and must be placed in sublink, and the second one is combined with the query block name.

The following example shows the effect of the hints with semi-join.

```

lightdb@postgres=# create table test1 (key1 int primary key, key2
int);
CREATE TABLE
lightdb@postgres=# create table test2 (key1 int primary key, key2
int);
CREATE TABLE
lightdb@postgres=#
lightdb@postgres=# EXPLAIN (COSTS false) select * from test1 where
exists (select * from test2 where test1.key1=test2.key1);
        QUERY PLAN
-----
Hash Join
Hash Cond: (test1.key1 = test2.key1)
->  Seq Scan on test1
->  Hash
        ->  Seq Scan on test2
(5 rows)

lightdb@postgres=# EXPLAIN (COSTS false) select * from
test1 where exists (select /*+semijoin*/ * from test2 where
test1.key1=test2.key1);
        QUERY PLAN
-----
Merge Semi Join
Merge Cond: (test1.key1 = test2.key1)
->  Index Scan using test1_pkey on test1 @"lt#1"
->  Index Only Scan using test2_pkey on test2 @"lt#0"
(4 rows)

lightdb@postgres=# EXPLAIN (COSTS false) select * from
test1 where exists (select /*+hash_sj*/ * from test2 where
test1.key1=test2.key1);

```

QUERY PLAN

```
-----
Hash Semi Join
Hash Cond: (test1.key1 = test2.key1)
-> Seq Scan on test1 @"lt#1"
-> Hash
    -> Seq Scan on test2 @"lt#0"
(5 rows)
```

lightdb@postgres=#

The following example shows the effect of the hints without semi-join.

```
lightdb@postgres=# create table tt1 (id int, t int, name
varchar(255));
CREATE TABLE
lightdb@postgres=# create table tt2 (id int , salary int);
CREATE TABLE
lightdb@postgres=# create index idx_t1_id on tt1(id);
CREATE INDEX
lightdb@postgres=# create index idx_t2_id on tt2(id);
CREATE INDEX
lightdb@postgres=#
lightdb@postgres=# EXPLAIN (COSTS false) select * from tt1 where
exists (select * from tt2 where tt1.id=tt2.id);
QUERY PLAN
```

```
-----
Nested Loop Semi Join
-> Seq Scan on tt1
-> Index Only Scan using idx_t2_id on tt2
    Index Cond: (id = tt1.id)
(4 rows)
```

```
lightdb@postgres=# EXPLAIN (COSTS false) select * from tt1 where
exists (select /*+no_semijoin*/ from tt2 where tt1.id=tt2.id);
QUERY PLAN
```

```
-----
Hash Join
Hash Cond: (tt1.id = tt2.id)
-> Seq Scan on tt1 @"lt#1"
-> Hash
    -> HashAggregate
        Group Key: tt2.id
    -> Seq Scan on tt2 @"lt#0"
(7 rows)
```

lightdb@postgres=#

The following example shows the effect of the hints with anti-join.

```
lightdb@postgres=# create table tt1 (id int, t int, name
varchar(255));
CREATE TABLE
lightdb@postgres=# create table tt2 (id int , salary int);
CREATE TABLE
lightdb@postgres=# EXPLAIN (COSTS false) select * from test1 where
not exists (select 1 from test2 where test1.key1=test2.key1);
```

QUERY PLAN

```
-----

   rows=2260 width=8)
-> Index Only Scan using test2_pkey on test2 @qb
   (cost=0.15..45.06 rows=2260 width=4)
   (4 rows)

lightdb@postgres=#

```

#### F.27.4.1.8.4. Hint for specify outer table of hashjoin

This hint "swap\_join\_inputs" specifies the outer table of hashjoin.

The following example shows the effect of "swap\_join\_inputs".

```

lightdb@postgres=# create table test1 (key1 int primary key, key2
int);
CREATE TABLE
lightdb@postgres=# create table test2 (key1 int primary key, key2
int);
CREATE TABLE
lightdb@postgres=# EXPLAIN (COSTS false) select * from test1, test2
where test1.key1 = test2.key1;
          QUERY PLAN

```

```

-----
Hash Join
Hash Cond: (test1.key1 = test2.key1)
-> Seq Scan on test1
-> Hash
       -> Seq Scan on test2
(5 rows)

```

```

lightdb@postgres=# EXPLAIN (COSTS false) select /*
+swap_join_inputs(test2)*/ from test1, test2 where test1.key1 =
test2.key1;
LOG:   lt_hint_plan:
used hint:
swap_join_inputs(test2@lt#0)
not used hint:
duplication hint:

```

error hint:

QUERY PLAN

```
-----
Hash Join
Hash Cond: (test2.key1 = test1.key1)
-> Seq Scan on test2 @"lt#0"
-> Hash
    -> Seq Scan on test1 @"lt#0"
(5 rows)
```

lightdb@postgres=#

Using this hint will enforce SQL to use hashjoin if possible. The following example shows it.

```
lightdb@postgres=# create table t_1(key1 int not null);
CREATE TABLE
lightdb@postgres=# create table t_2(key1 int not null);
CREATE TABLE
lightdb@postgres=# explain select /*swap_join_inputs(t_2)*/ from
t_1,t_2 where t_1.key1=t_2.key1;
QUERY PLAN
```

```
-----
Merge Join (cost=359.57..860.00 rows=32512 width=8)
Merge Cond: (t_1.key1 = t_2.key1)
-> Sort (cost=179.78..186.16 rows=2550 width=4)
    Sort Key: t_1.key1
    -> Seq Scan on t_1 (cost=0.00..35.50 rows=2550 width=4)
-> Sort (cost=179.78..186.16 rows=2550 width=4)
    Sort Key: t_2.key1
    -> Seq Scan on t_2 (cost=0.00..35.50 rows=2550 width=4)
(8 rows)
```

```
lightdb@postgres=# explain select /*+swap_join_inputs(t_2)*/ from
t_1,t_2 where t_1.key1=t_2.key1;
LOG:  lt_hint_plan:
used hint:
swap_join_inputs(t_2@lt#0)
not used hint:
duplication hint:
error hint:
```

QUERY PLAN

```
-----
Hash Join (cost=67.38..1247.18 rows=32512 width=8)
Hash Cond: (t_2.key1 = t_1.key1)
-> Seq Scan on t_2 @"lt#0" (cost=0.00..35.50 rows=2550 width=4)
-> Hash (cost=35.50..35.50 rows=2550 width=4)
    -> Seq Scan on t_1 @"lt#0" (cost=0.00..35.50 rows=2550
width=4)
(5 rows)
```

lightdb@postgres=#

When used with the leading hint, parts of the leading hint that conflict with these hints will be ignored. The following example shows it.

```
lightdb@postgres=# EXPLAIN (COSTS false) select /*+ leading(test1
test2) swap_join_inputs(test2)*/ from test1, test2 where
test1.key1 = test2.key1;
INFO:  lt_hint_plan: leading hint conflict with swap_join_inputs
hint, ignore leading hint
DETAIL: use swap_join_hint(test2@lt#0)
LOG:  lt_hint_plan:
used hint:
Leading((test1@lt#0 test2@lt#0))
swap_join_inputs(test2@lt#0)
not used hint:
duplication hint:
error hint:
```

QUERY PLAN

```
-----
Hash Join
Hash Cond: (test2.key1 = test1.key1)
-> Seq Scan on test2 @"lt#0"
-> Hash
      -> Seq Scan on test1 @"lt#0"
(5 rows)
```

```
lightdb@postgres=#
```

When used with the join method hint, this hint can't be used if the join method hint specifies a non-hashjoin method. The following example shows it.

```
lightdb@postgres=# EXPLAIN (COSTS false) select /*+ nestloop(test1
test2) swap_join_inputs(test2)*/ from test1, test2 where
test1.key1 = test2.key1;
LOG:  lt_hint_plan:
used hint:
NestLoop(test1@lt#0 test2@lt#0)
not used hint:
swap_join_inputs(test2@lt#0)
duplication hint:
error hint:
```

QUERY PLAN

```
-----
Nested Loop
-> Seq Scan on test1 @"lt#0"
-> Index Scan using test2_pkey on test2 @"lt#0"
      Index Cond: (key1 = test1.key1)
(4 rows)
```

```
lightdb@postgres=#
```

This hint shouldn't be used for semij-join and anti-join, because semi-join and anti-join can't change outer table. When used with semi-join and anti-join hint, this hint will be ignored. The following example shows it.

```
lightdb@postgres=# EXPLAIN (COSTS false) select/*
+swap_join_inputs(test2@qb)*/ * from test1 where exists ( select/
```

```
*+semijoin qb_name(qb)*/ * from test2 where test1.key1 =
test2.key1);
INFO:  lt_hint_plan: special join hint conflict with
swap_join_inputs hint, ignore swap_join_inputs hint
DETAIL: ignore swap_join_hint(test2@qb), use semijoin(@qb)
LOG:  lt_hint_plan:
used hint:

->  Index Scan using test1_pkey on test1 @"lt#0"
->  Index Only Scan using test2_pkey on test2 @qb
(4 rows)
```

lightdb@postgres=#

#### F.27.4.1.8.5. Hint to preserve the order of predicate evaluation

This hint "ordered\_predicates" forces the optimizer to preserve the order of predicate evaluation, except for predicates used as index keys. Use this hint for the WHERE clause of SELECT statements.

You can override these default evaluation rules using the ordered\_predicates hint, and your WHERE clause items will then be evaluated in the order that they appear in the query. The ordered\_predicates hint is commonly used in cases where a function is used in the WHERE clause of a query. It is also very useful in cases where you know the most restrictive predicates and you want Lightdb to evaluate these first.

The following example shows the effect of "ordered\_predicates".

```
lightdb@postgres=# create table test1 (key1 int, key2 int);
CREATE TABLE
lightdb@postgres=# create table test2 (key1 int, key2 int);
CREATE TABLE
lightdb@postgres=# EXPLAIN (COSTS false) select * from test1 where
mod(key1,10)=2 and key2=2;
```

QUERY PLAN

```
-----
Seq Scan on test1
  Filter: ((key2 = 2) AND (mod(key1, 10) = 2))
(2 rows)
```

```
lightdb@postgres=# EXPLAIN (COSTS false) select /*
+ordered_predicates*/ * from test1 where mod(key1,10)=2 and key2=2;
```

QUERY PLAN

```
-----
Seq Scan on test1 @"lt#0"
  Filter: ((mod(key1, 10) = 2) AND (key2 = 2))
(2 rows)
```

lightdb@postgres=#

This hint will not affect predicates that transitively generated by the optimizer.

In the following example, "b.key2 = 1" is regenerated by the optimizer, so its order can't be reserved.

```
lightdb@postgres=# EXPLAIN (COSTS false) select * from test1 a left
join test2 b on a.key1=b.key1 and a.key2=b.key2 where mod(b.key2,
10) = 2 and b.key2 = 1;
```

QUERY PLAN

```
-----
Nested Loop
  Join Filter: (a.key1 = b.key1)
  -> Seq Scan on test2 b
      Filter: ((key2 = 1) AND (mod(key2, 10) = 2))
  -> Seq Scan on test1 a
      Filter: (key2 = 1)
(6 rows)
```

```
lightdb@postgres=# EXPLAIN (COSTS false) select/*
+ordered_predicates*/ * from test1 a left join test2 b on
a.key1=b.key1 and a.key2=b.key2 where mod(b.key2, 10) = 2 and
b.key2 = 1;
```

QUERY PLAN

```
-----
Nested Loop
  Join Filter: (a.key1 = b.key1)
  -> Seq Scan on test2 b @"lt#0"
      Filter: ((key2 = 1) AND (mod(key2, 10) = 2))
  -> Seq Scan on test1 a @"lt#0"
      Filter: (key2 = 1)
(6 rows)
```

```
lightdb@postgres=#
```

#### F.27.4.1.8.6. Hint to control optimization about pull up sublink

The optimization about pull up sublink is an RBO. it will pull up sublink if it is possible. So there is no need to implement "unnest" hint, we only support syntax here.

The "no\_unnest" hint can be used to force to not pull up sublink.

The following example shows the effect of "no\_unnest".

```
lightdb@postgres=# create table test1 (key1 int, key2 int);
CREATE TABLE
lightdb@postgres=# create table test2 (key1 int, key2 int);
CREATE TABLE
lightdb@postgres=# EXPLAIN (COSTS false) select * from test1 where
exists(select * from test2 where test1.key1=test2.key1);
```

QUERY PLAN

```
-----
Hash Join
  Hash Cond: (test1.key1 = test2.key1)
  -> Seq Scan on test1
  -> Hash
      -> HashAggregate
          Group Key: test2.key1
          -> Seq Scan on test2
(7 rows)
```

```
lightdb@postgres=# EXPLAIN (COSTS false) select * from
test1 where exists(select/*+no_unnest*/ * from test2 where
test1.key1=test2.key1);
```

```
QUERY PLAN
```

```
-----
Seq Scan on test1 @"lt#1"
  Filter: (alternatives: SubPlan 1 or hashed SubPlan 2)
  SubPlan 1
    -> Seq Scan on test2 @"lt#0"
        Filter: (test1.key1 = key1)
  SubPlan 2
    -> Seq Scan on test2 test2_1 @"lt#0"
(7 rows)
```

```
lightdb@postgres=#
```

#### F.27.4.1.8.7. Hint to control parallel join mode

Now 'pq\_distribute' hint is only use for parallel hash join, and only this usage ('pq\_distribute(inner\_table none broadcast)') works.

The usage ('pq\_distribute(inner\_table hash hash)') is supported, but not work.

When used with 'leading' hint, it will be used only if the specified table is the inner table after using 'leading' hint.

The following example shows the effect of "pq\_distribute".

```
lightdb@postgres=# create table t1 (id int, val text);
CREATE TABLE
lightdb@postgres=# create table t2 (id int, val text);
CREATE TABLE
lightdb@lt_test=# /*+set(parallel_tuple_cost 0)
set(parallel_setup_cost 0) set(min_parallel_table_scan_size
0) set(min_parallel_index_scan_size 0)
set(max_parallel_workers_per_gather 8)*/
lightdb@lt_test=# EXPLAIN (COSTS false) SELECT /*+ leading(t1 t2)
hashjoin(t1 t2)*/ * FROM t1 join t2 on t1.id=t2.id;
QUERY PLAN
```

```
-----
Gather
  Workers Planned: 3
  -> Parallel Hash Join
      Hash Cond: (t1.id = t2.id)
      -> Parallel Seq Scan on t1 @"lt#0"
      -> Parallel Hash
          -> Parallel Seq Scan on t2 @"lt#0"
(7 rows)
```

```
lightdb@lt_test=# /*+set(parallel_tuple_cost 0)
set(parallel_setup_cost 0) set(min_parallel_table_scan_size
0) set(min_parallel_index_scan_size 0)
set(max_parallel_workers_per_gather 8)*/
lightdb@lt_test=# EXPLAIN (COSTS false) select/*+leading(t1 t2)
hashjoin(t1 t2) pq_distribute(t2 none broadcast)*/ * from t1 join
t2 on t1.id=t2.id;
QUERY PLAN
```

```
-----
Gather
```

```

Workers Planned: 3
-> Hash Join
    Hash Cond: (t1.id = t2.id)
    -> Parallel Seq Scan on t1 @"lt#0"
    -> Hash
        -> Seq Scan on t2 @"lt#0"
(7 rows)

```

lightdb@lt\_test=#

When used with 'swap\_join\_inputs' hint, it will always be used if 'swap\_join\_inputs' hint is used. It is different from oracle, in oracle, 'pq\_distribute' will not work if the specified table is the inner table after using 'swap\_join\_inputs'.

```

lightdb@lt_test=# /*+set(parallel_tuple_cost 0)
set(parallel_setup_cost 0) set(min_parallel_table_scan_size
0) set(min_parallel_index_scan_size 0)
set(max_parallel_workers_per_gather 8)*/
EXPLAIN (COSTS false) select/*+leading(t1 t2) hashjoin(t1
t2) pq_distribute(t1 none broadcast)*/ * from t1 join t2 on
t1.id=t2.id;

```

QUERY PLAN

```

-----
Gather
  Workers Planned: 3
  -> Parallel Hash Join
      Hash Cond: (t1.id = t2.id)
      -> Parallel Seq Scan on t1 @"lt#0"
      -> Parallel Hash
          -> Parallel Seq Scan on t2 @"lt#0"
(7 rows)

```

```

lightdb@lt_test=# /*+set(parallel_tuple_cost 0)
set(parallel_setup_cost 0) set(min_parallel_table_scan_size
0) set(min_parallel_index_scan_size 0)
set(max_parallel_workers_per_gather 8)*/
EXPLAIN (COSTS false) select/*+leading(t1 t2) hashjoin(t1 t2)
pq_distribute(t1 none broadcast) swap_join_inputs(t2)*/ * from t1
join t2 on t1.id=t2.id;

```

QUERY PLAN

```

-----
Gather
  Workers Planned: 3
  -> Hash Join
      Hash Cond: (t2.id = t1.id)
      -> Parallel Seq Scan on t2 @"lt#0"
      -> Hash
          -> Seq Scan on t1 @"lt#0"
(7 rows)

```

```

lightdb@lt_test=# /*+set(parallel_tuple_cost 0)
set(parallel_setup_cost 0) set(min_parallel_table_scan_size
0) set(min_parallel_index_scan_size 0)
set(max_parallel_workers_per_gather 8)*/
EXPLAIN (COSTS false) select/*+leading(t1 t2) hashjoin(t1 t2)
pq_distribute(t2 none broadcast) swap_join_inputs(t2)*/ * from t1
join t2 on t1.id=t2.id;

```

QUERY PLAN

```

-----
Gather
  Workers Planned: 3
  -> Hash Join
      Hash Cond: (t2.id = t1.id)
      -> Parallel Seq Scan on t2 @"lt#0"
      -> Hash
          -> Seq Scan on t1 @"lt#0"
(7 rows)

```

lightdb@lt\_test=#

Without specifying the order of join, 'pq\_distribute' hint might be used but doesn't work, because it can only work when the specified table is the inner table and the join is a parallel hash join. If the cost of another path which the specified table is the outer table is lower, the optimizer will choose another path.

```

lightdb@lt_test=# /*+set(parallel_tuple_cost 0)
set(parallel_setup_cost 0) set(min_parallel_table_scan_size
0) set(min_parallel_index_scan_size 0)
set(max_parallel_workers_per_gather 8)*/
EXPLAIN (COSTS false) select/*+hashjoin(t1 t2)pq_distribute(t2 none
broadcast)*/ * from t1 join t2 on t1.id=t2.id;
          QUERY PLAN

```

```

-----
Gather
  Workers Planned: 3
  -> Parallel Hash Join
      Hash Cond: (t2.id = t1.id)
      -> Parallel Seq Scan on t2 @"lt#0"
      -> Parallel Hash
          -> Parallel Seq Scan on t1 @"lt#0"
(7 rows)

```

```

lightdb@lt_test=# /*+set(parallel_tuple_cost 0)

#### F.27.4.1.8.8. Hint about pushing down clauses with sublink

In LightDB, the optimization about pushing down clauses with sublink is an RBO. it will push down clauses with sublink if it is possible.

The "no\_push\_subq" hint can be used to force to not push down clauses with sublink.

The "push\_subq" hint can be used to force to push down clauses with sublink. But because LightDB will push down clauses with sublink if it is possible, there is no need to use it. if you use it, it will be marked used when it can be used.

The following example shows the effect of "no\_push\_subq". The "push\_subq" hint's usage is similar to "no\_push\_subq".

```
create table test_no_push_subq1 as select * from pg_class order by
oid limit 100;
create table test_no_push_subq2 as select * from pg_class order by
oid limit 100;
create table test_no_push_subq3 as select * from pg_class order by
oid limit 100;
create table test_no_push_subq4 as select * from pg_class order by
oid limit 100;
lightdb@postgres=# EXPLAIN (COSTS false)
lightdb@postgres=# select a.oid from test_no_push_subq1 a join
test_no_push_subq3 b on a.relytype =b.relytype and a.oid = b.oid

#### F.27.4.1.8.9. Hint to ignore a unique key violation

The "ignore\_row\_on\_dupkey\_index" hint can be used to ignore a unique key violation for a specified set of columns or for a specified index. Currently using this hint is the same as using 'on conflict do nothing' clause. If you specify this hint when inserting data with DML error logging enabled, then the unique key violation is not logged and does not cause statement termination.

The semantic effect of this hint results in error messages if specific rules are violated:

- You must specify exactly one index. If you specify no index, then the statement causes LT008(oracle is ORA-38912). If you specify more than one index, then the statement causes LT010(oracle is ORA-38915).
- If you specify index, then the index must exist and be unique. Otherwise, the statement causes LT009(oracle is ORA-38913).
- The IGNORE\_ROW\_ON\_DUPKEY\_INDEX hint applies only to single-table INSERT operations. It is not supported for UPDATE, DELETE, MERGE(do not support hint yet, will ignore), or multitable insert operations, and will report LT011(oracle is ORA-38917).
- If the specified columns have more than one index, then the statement causes LT010(oracle does not have this because you cannot have more than one index on the same field).
- Cannot be used with an on conflict clause and will result in an LT011 error (oracle does not have an on conflict clause).

The following example shows the effect of the "ignore\_row\_on\_dupkey\_index" hint:

```

create table test_ignore_dupkey(key1 int, key2 int, key3 int, key4
int);
create unique index test_ignore_dupkey_ui1 on
test_ignore_dupkey(key1, key2);
create unique index test_ignore_dupkey_ui2 on
test_ignore_dupkey(key3, key4);
create index test_ignore_dupkey_i on test_ignore_dupkey(key3);

lightdb@postgres=# insert into test_ignore_dupkey values(1, 1, 1,

**F.27.4.1.8.10. Hint about pushing pred to subquery**

If you have a non-mergeable view or subquery (possible because of a `no_merge` hint) in your query, how should you operate the join from other tables? should you create one large view result and join it once (`no_push_pred`) or should you push the join predicate down into the view definition and recreate the view result set for every driving row from another table (`push_pred` and must be `nestloop`).

The "`no_push_pred`" hint instructs the optimizer not to push a join predicate into the view.

LightDB does not support to push a join predicate into the view yet. Now this is only supported for Oracle compatibility. So if you use "`no_push_pred`" hint, it will always work.

The following example shows the usage of the "`no_push_pred`" hint:

```
create table test_no_push_pred1 (key1 int primary key, key2 int);
create table test_no_push_pred2 (key1 int primary key, key2 int);
create table test_no_push_pred3 (key1 int primary key, key2 int);
```

```
set enable_hashjoin to off;
set enable_mergejoin to off;
```

```
lightdb@test_o=# EXPLAIN (COSTS false)
lightdb@test_o=# select /*+leading(a)*/ from test_no_push_pred1 a
  join (select * from test_no_push_pred2 order by key1 limit 1) b on
  a.key1 =b.key2;
```

QUERY PLAN

```

#### F.27.4.1.8.11. Hint about star transformation

Star transformation is an optimizer transformation that avoids full table scans of fact tables in a star schema (star schema divides data into facts and dimensions). In joins of fact and dimension tables, a star transformation can avoid a full scan of a fact table. The star transformation improves performance by fetching only relevant fact rows that join to the constraint dimension rows. In some cases, queries have restrictive filters on other columns of the dimension tables. The combination of filters can dramatically reduce the data set that the database processes from the fact table.

The "no\_star\_transformation" hint instructs the optimizer not to perform star query transformation.

LightDB does not support star transformation yet. Now "no\_star\_transformation" hint is only supported for Oracle compatibility. So if you use "no\_star\_transformation" hint, it will always work.

The following example shows the usage of the "no\_star\_transformation" hint:

```
CREATE TABLE times (
    time_id NUMBER PRIMARY KEY,
    calendar_quarter_desc VARCHAR2(20)
);
```

```
CREATE TABLE customers (
    cust_id NUMBER PRIMARY KEY,
    cust_city VARCHAR2(20),
    cust_state_province VARCHAR2(20)
);
```

```
CREATE TABLE channels (
    channel_id NUMBER PRIMARY KEY,
    channel_class VARCHAR2(20),
    channel_desc VARCHAR2(20)
);
```

```
CREATE TABLE sales (
    time_id NUMBER REFERENCES times(time_id),
    cust_id NUMBER REFERENCES customers(cust_id),
    channel_id NUMBER REFERENCES channels(channel_id),
    amount_sold NUMBER
);
```

```
lightdb@postgres=# EXPLAIN (COSTS false) SELECT/*
+no_star_transformation*/ ch.channel_class, c.cust_city,
t.calendar_quarter_desc,
    SUM(s.amount_sold) sales_amount

#### F.27.4.1.8.12. Hint about direct-path insert

During direct-path INSERT operations, the database appends the inserted data after existing data in the table. Data is written directly into data files, bypassing the buffer cache. Free space in the table is not reused, and referential integrity constraints are ignored. Direct-path INSERT can perform significantly better than conventional insert.

The "append" hint instructs the optimizer to use direct-path INSERT with the subquery syntax of the INSERT statement.

LightDB does not support direct-path INSERT yet. Now "append" hint is only supported for Oracle compatibility. So if you use "append" hint, it will always be unused.

The following example shows the usage of the "append" hint:

```

create table test_append(key1 int, key2 int, key3 int, key4 int);
create table test_append1(key1 int, key2 int, key3 int, key4 int);

insert into test_append1 values(1,2,3,4);
insert into test_append1 values(11,21,31,41);
insert into test_append1 values(111,211,311,411);

lightdb@test_oracle_lt_hint_plan=# EXPLAIN (COSTS FALSE) insert/*

### F.27.4.2. GUC parameters for lt\_hint\_plan

GUC parameters below affect the behavior of lt\_hint\_plan.

**Table F.13. GUC parameters for lt\_hint\_plan**

Parameter name	description	Default
lt_hint_plan.enable_hint	Enables lt_hint_plan.	on
lt_hint_plan.enable_hinting_by_table	Enables hinting by table. true or false.	off
lt_hint_plan.parse_messages	Specifies the log level of hint parse error. Valid values are error, warning, notice, info, log, debug.	INFO
lt_hint_plan.debug_controls	Controls debug print and verbosity. Valid vaiues are off, on, detailed and verbose.	off
lt_hint_plan.messages	Specifies message level of debug print. Valid values are error, warning, notice, info, log, debug.	INFO
lt_hint_plan.show_verbose_info	Show verbose info in debug print.	on

## F.27.5. Details in hinting

### F.27.5.1. Syntax and placement

For global level hint, `lt_hint_plan` reads only the first block comment at sql head(before first character of sql)

```
lightdb@postgres=# /*+ indexscan(b)*/ explain select * from
ltbench_accounts b where b.aid>10;
                                QUERY PLAN
```

```
-----
Index Scan using ltbench_accounts_pkey on ltbench_accounts b
 (cost=0.29..3666.12
 rows=99990 width=97)
Index Cond: (aid > 10)
(2 rows)
```

```
lightdb@postgres=#
```

For stmt level hint, `lt_hint_plan` reads hints from only the first block comment after select, update, delete, insert keyword. hint only works on current query block without using `qb_name`. In the following example HashJoin(a b) and SeqScan(a) are parsed as hints but IndexScan(a) and IndexScan(b) are not.

```
lightdb@postgres=# /*+
lightdb@postgres*#   HashJoin(a b)
lightdb@postgres*#   */
lightdb@postgres-# /*+ IndexScan(a) */
lightdb@postgres-# EXPLAIN SELECT /*+ SeqScan(a) */ *
lightdb@postgres-#   FROM /*+ IndexScan(b) */ltbench_branches b
lightdb@postgres-#   JOIN ltbench_accounts a ON b.bid = a.bid
lightdb@postgres-#   ORDER BY a.aid;
                                QUERY PLAN
```

```
-----
----
Sort  (cost=24236.84..24486.84 rows=100000 width=461)
Sort Key: a.aid
-> Hash Join  (cost=1.02..4016.02 rows=100000 width=461)
      Hash Cond: (a.bid = b.bid)
        -> Seq Scan on ltbench_accounts a  (cost=0.00..2640.00
      rows=100000 width=
97)
          -> Hash  (cost=1.01..1.01 rows=1 width=364)
                -> Seq Scan on ltbench_branches b  (cost=0.00..1.01
      rows=1 width=36
4)
(7 rows)
```

```
lightdb@postgres=#
```

### F.27.5.2. Using with PL/pgSQL

`lt_hint_plan` works for queries in PL/pgSQL scripts with some restrictions.

- Hints affect only on the following kind of queries.
  - Queries that returns one row. (SELECT, INSERT, UPDATE and DELETE)
  - Queries that returns multiple rows. (RETURN QUERY)
  - Dynamic SQL statements. (EXECUTE)
  - Cursor open. (OPEN)
  - Loop over result of a query (FOR)
- A hint comment have to be placed after the first word in a query as the following since preceding comments are not sent as a part of the query.

```
lightdb@postgres=# CREATE FUNCTION hints_func(integer) RETURNS
integer AS $$
lightdb@postgres$# DECLARE
lightdb@postgres$#     id integer;
lightdb@postgres$#     cnt integer;
lightdb@postgres$# BEGIN
lightdb@postgres$#     SELECT /*+ NoIndexScan(a) */ aid
lightdb@postgres$#         INTO id FROM ltbench_accounts a WHERE
lightdb@postgres$#     aid = $1;
lightdb@postgres$#     SELECT /*+ SeqScan(a) */ count(*)
lightdb@postgres$#         INTO cnt FROM ltbench_accounts a;
lightdb@postgres$#     RETURN id + cnt;
lightdb@postgres$# END;
lightdb@postgres$# $$ LANGUAGE plpgsql;
```

### F.27.5.3. Letter case in the object names

Like the way LightDB handles object names, `lt_hint_plan` will convert object names to lowercase. Therefore an object name TBL in a hint matches TBL, tbl or Tbl in database. With quotes, `lt_hint_plan` will not convert object names to lowercase. Therefore an object name "TBL" in a hint matches only "TBL" in database and does not match any unquoted names like TBL, tbl or Tbl.

### F.27.5.4. Escaping special characters in object names

The objects as the hint parameter should be enclosed by double quotes if they includes parentheses, double quotes and white spaces. The escaping rule is the same as LightDB.

### F.27.5.5. Distinction between multiple occurrences of a table

`lt_hint_plan` identifies the target object by using aliases if exists. This behavior is usable to point a specific occurrence among multiple occurrences of one table.

```
lightdb@postgres=# /*+ HashJoin(t1 t1) */
lightdb@postgres-# EXPLAIN SELECT * FROM s1.t1
lightdb@postgres-# JOIN public.t1 ON (s1.t1.id=public.t1.id);
INFO:  hint syntax error at or near "HashJoin(t1 t1)"
DETAIL:  Relation name "t1" is ambiguous.
...
lightdb@postgres=# /*+ HashJoin(pt st) */
lightdb@postgres-# EXPLAIN SELECT * FROM s1.t1 st
lightdb@postgres-# JOIN public.t1 pt ON (st.id=pt.id);
QUERY PLAN
-----
```

```

Hash Join (cost=64.00..1112.00 rows=28800 width=8)
Hash Cond: (st.id = pt.id)
-> Seq Scan on t1 st (cost=0.00..34.00 rows=2400 width=4)
-> Hash (cost=34.00..34.00 rows=2400 width=4)
    -> Seq Scan on t1 pt (cost=0.00..34.00 rows=2400
width=4)

```

### F.27.5.6. Underlying tables of views or rules

Hints are applicable on views itself, and they can affect the queries within if the object names match the object names in the expanded query on the view when used as global level hint. but for stmt level hint, it need use qb\_name hint to manipulate talbes in view.

```

create view test_v as select /*+qb_name(qb)*/ * from t1 where id
>10;
EXPLAIN (COSTS false) select /*+indexscan(t1)*/ * from test_v;
LOG:  lt_hint_plan:
used hint:
not used hint:
IndexScan(t1@lt#0)
duplication hint:
error hint:

```

QUERY PLAN

```

-----
Seq Scan on t1 @qb
Filter: (id > 10)
(2 rows)

```

```

EXPLAIN (COSTS false) select /*+indexscan(t1@qb)*/ * from test_v;

not used hint:
duplication hint:
error hint:

```

QUERY PLAN

```

-----
Index Scan using t1_pkey on t1 @qb
Index Cond: (id > 10)
(2 rows)

```

### F.27.5.7. Inheritance tables

Hints can point only the parent of an inheritance tables and the hint affect all the inheritance. Hints simultaneously point directly to children are not in effect.

### F.27.5.8. Hinting on multistatements

For global level hint, one multistatement can have exactly one hint comment and the hints affects all of the individual statement in the multistatement. Notice that the seemingly multistatement on the interactive interface of ltsql is internally a sequence of single statements so hints affects only on the statement just following. For stmt level hint, it is same with single statement.

### F.27.5.9. VALUES expressions

VALUES expressions in FROM clause are named as \*VALUES\* internally so it is hintable if it is the only VALUES in a query. Two or more VALUES expressions in a query seems distinguishable looking its explain result. But in reality it is mere a cosmetic and they are not distinguishable.

```
lightdb@postgres=# /*+ MergeJoin(*VALUES*_1 *VALUES*) */
      EXPLAIN SELECT * FROM (VALUES (1, 1), (2, 2)) v (a, b)
      JOIN (VALUES (1, 5), (2, 8), (3, 4)) w (a, c) ON v.a = w.a;
INFO:  lt_hint_plan: hint syntax error at or near
      "MergeJoin(*VALUES*_1 *VALUES*) "
DETAIL:  Relation name "*VALUES*" is ambiguous.
      QUERY PLAN
-----
      Hash Join  (cost=0.05..0.12 rows=2 width=16)
      Hash Cond: ("*VALUES*_1".column1 = "*VALUES*".column1)
      -> Values Scan on "*VALUES*_1"  (cost=0.00..0.04 rows=3
width=8)
      -> Hash  (cost=0.03..0.03 rows=2 width=8)
      -> Values Scan on "*VALUES*"  (cost=0.00..0.03 rows=2
width=8)
```

### F.27.5.10. Cost value in explain may wrong

lt\_hint\_plan makes the execution plan choose the desired path by increasing the cost of the undesired path (cost += disable\_cost, disable\_cost=1.0e10).

Sometimes even if hint is used, sql will not execute as hinted because the desired path is not available, such as using indexscan hint on a table without index. In this case the cost in explain is not accurate.

The actual cost can be obtained by subtracting the disable\_cost.

```
lightdb@postgres=# create table test(id int);
CREATE TABLE
lightdb@postgres=# explain select * from test where id=1;
      QUERY PLAN
-----
      Seq Scan on test  (cost=0.00..41.88 rows=13 width=4)
      Filter: (id = 1)
      (2 rows)

lightdb@postgres=# explain select /*+indexscan(test)*/ from test
      where id=1;
      QUERY PLAN
-----
```

```
Seq Scan on test @"lt#0" (cost=10000000000.00..10000000041.88
 rows=13 width=4)
Filter: (id = 1)
(2 rows)
```

```
lightdb@postgres=#
```

## F.27.6. Subqueries

Subqueries in the following context occasionally can be hinted using the name "ANY\_subquery".

```
IN (SELECT ... {LIMIT | OFFSET ...} ...)
= ANY (SELECT ... {LIMIT | OFFSET ...} ...)
= SOME (SELECT ... {LIMIT | OFFSET ...} ...)
```

For these syntaxes, planner internally assigns the name to the subquery when planning joins on tables including it, so join hints are applicable on such joins using the implicit name as the following.

```
lightdb@postgres=# /*+HashJoin(a1 ANY_subquery)*/
lightdb@postgres=# EXPLAIN SELECT *
lightdb@postgres=# FROM ltbench_accounts a1
lightdb@postgres=# WHERE aid IN (SELECT bid FROM ltbench_accounts
a2 LIMIT 10);
```

QUERY PLAN

```
-----
Hash Semi Join (cost=0.49..2903.00 rows=1 width=97)
Hash Cond: (a1.aid = a2.bid)
-> Seq Scan on ltbench_accounts a1 (cost=0.00..2640.00
rows=100000 width=97)
-> Hash (cost=0.36..0.36 rows=10 width=4)
-> Limit (cost=0.00..0.26 rows=10 width=4)
-> Seq Scan on ltbench_accounts a2
(cost=0.00..2640.00 rows=100000 width=4)
```

### F.27.6.1. Using IndexOnlyScan hint

Index scan may unexpectedly performed on another index when the index specified in IndexOnlyScan hint cannot perform index only scan.

### F.27.6.2. Behavior of NoIndexScan

NoIndexScan hint involves NoIndexOnlyScan.

### F.27.6.3. Parallel hint and UNION

A UNION can run in parallel only when all underlying subqueries are parallel-safe. Conversely enforcing parallel on any of the subqueries let a parallel-executable UNION run in parallel. Meanwhile, a parallel hint with zero workers hinhbits a scan from executed in parallel.

### F.27.6.4. Setting It\_hint\_plan parameters by Set hints

It\_hint\_plan paramters change the behavior of itself so some parameters doesn't work as expected.

- Hints to change enable\_hint, enable\_hint\_tables are ignored even though they are reported as "used hints" in debug logs.
- Setting debug\_print and message\_level works from midst of the processing of the target query.

## F.27.6.5. Scan and Join Hints on Subqueries

Scan hints, join hints(include join method and join order hints) and rows hint on referenced subquery(Mergeable) are ignored unless the subquery contains a single table. If the subquery contains a single table, the scan path hint or join hint on it applies to the table inside the subquery.

```
lightdb@postgres=# create table test1(id int primary key, value
int);
CREATE TABLE
lightdb@postgres=# create table test2(id int primary key, value
int);
CREATE TABLE
lightdb@postgres=# EXPLAIN (COSTS false) select * from test1,
(select * from (select * from test2) x) y where test1.id=y.id;
QUERY PLAN
```

```
-----
Hash Join
Hash Cond: (test1.id = test2.id)
-> Seq Scan on test1
-> Hash
    -> Seq Scan on test2
(5 rows)
```

```
lightdb@postgres=# EXPLAIN (COSTS false) select /*+indexscan(y)*/
* from test1,(select * from (select * from test2) x) y where
test1.id=y.id;
QUERY PLAN
```

```
-----
Hash Join
Hash Cond: (test2.id = test1.id)
-> Index Scan using test2_pkey on test2 @"lt#2"
-> Hash
    -> Seq Scan on test1 @"lt#0"
(5 rows)
```

```
lightdb@postgres=#
```

## F.27.7. Compatible with canopy

Now `lt_hint_plan` is compatible with canopy, it can be used to control execution plan involving Distributed Tables and Reference Tables.

### F.27.7.1. Hint state

To view the usage state of hints on data nodes, first you need to turn on `debug_print` on datanode, then set `canopy.log_remote_commands` to on, and finally set `canopy.worker_min_messages` to 'log' and `client_min_messages` to 'log' or set `lt_hint_plan.message_level` to 'notice'. The following example shows it.

```
lightdb@postgres=# CREATE TABLE t1 (id int PRIMARY KEY, val int);
CREATE TABLE
lightdb@postgres=# SELECT create_distributed_table('t1', 'id');
create_distributed_table
```

```
-----
(1 row)
```

```

lightdb@postgres=# set lt_hint_plan.message_level = 'notice';
SET
lightdb@postgres=# set canopy.log_remote_commands=on;
SET
lightdb@postgres=# explain select /*+indexscan(t1)*/ from t1 where
id=10;
NOTICE:  lt_hint_plan:

```

## F.27.7.2. Limitations

CTEs and subqueries that cannot be pushed down and do not contain references to the outer query are planned by recursively calling the planner function with the subquery as the parse tree. The resulting

plan are executed independently, and SQL statement has been splited. Therefore hints that act on both out query and subquery, and no\_merge, semijoin/antijoin hints that act on subqueries will have no effect. The following example shows it.

```
lightdb@postgres=# CREATE TABLE t1 (id int PRIMARY KEY, val int);
CREATE TABLE
lightdb@postgres=# CREATE TABLE t2 (id int PRIMARY KEY, val int);
CREATE TABLE
lightdb@postgres=# SELECT create_distributed_table('t1', 'id');

lightdb@postgres=#

```

## F.27.8. Errors

`It_hint_plan` ignores invalid hint and continues to find next valid hint. When it finds an invalid hint, the error will be reported but only when it is an explain SQL. Followings are the typical errors.

### F.27.8.1. Syntax errors

Any syntactical errors or wrong hint names are reported as an syntax error. These errors are reported in the server log with the message level which specified by `lt_hint_plan.message_level` if `lt_hint_plan.debug_print` is on and above. Keyword that started with digit will not be a hint name, it will not be reported as an syntax error, but will be ignored.

### F.27.8.2. Object misspecifications

Object misspecifications results silent ingorance of the hints. This kind of error is reported as "not used hints" in the server log by the same condition to syntax errors.

### F.27.8.3. Redundant or conflicting hints

For same query block, one hint will be active when redundant hints, no hint will be active when hints conflicting with each other. For diffent query block, when redundant hints or hints conflicting with each other, only sub query's hint will be active. No matter when redundant hints or hints conflicting with each other, This kind of error is reported as "duplication hints" in the server log by the same condition to syntax errors. if `qb_name` hint conflict , both will be ignored.

### F.27.8.4. Nested comments

For global level hint, hint comment cannot include another block comment within. If `lt_hint_plan` finds it, differently from other erros, it stops parsing and abandans all hints already parsed. This kind of error is reported in the same manner as other errors. For stmt level hint, hint comment cannot include another block comment within. it will ignore `'/*'` in hint comment. if report error, it only affect current query block's hint.

```
lightdb@postgres=# explain select * from t1 ,(select * from t2
  where id >10) as tt where exists (select /*+ /*+seqscan(t1)*/ */
  from t3 where id>1);;

```

## F.27.9. Functional limitations

### F.27.9.1. Influences of some of planner GUC parameters

The planner does not try to consider joining order for FROM clause entries more than from\_collapse\_limit. It\_hint\_plan cannot affect joining order as expected for the case.

### F.27.9.2. Hints trying to enforce unexecutable plans

Planner chooses any executable plans when the enforced plan cannot be executed.

- FULL OUTER JOIN to use nested loop
- To use indexes that does not have columns used in quals
- To do TID scans for queries without ctid conditions

### F.27.9.3. Queries in ECPG

ECPG removes comments in queries written as embedded SQLs so hints cannot be passed form those queries. The only exception is that EXECUTE command passes given string unmodified. Please consider hint tables in the case.

### F.27.9.4. Work with It\_stat\_statements

It\_stat\_statements generates a query id ignoring comments. As the result the identical queires with different hints are summerized as the same query.

## F.27.10. Hint list

The available hints are listed below.

**Table F.14. Hints list**

Group	Format	Description
Scan method	SeqScan(table) full(table)	Forces sequential scan on the table
	TidScan(table)	Forces TID scan on the table.
	IndexScan(table[ index...]) index(table[ index...])	Forces index scan on the table. Restricts to specified indexes if any.

Group	Format	Description
	IndexOnlyScan(table[ index...])	Forces index only scan on the table. Restricts to specified indexes if any. Index scan may be used if index only scan is not available.
	BitmapScan(table[ index...])	Forces bitmap scan on the table. Restricts to specified indexes if any.
	IndexScanRegexp(table[ POSIX Regexp...]) IndexOnlyScanRegexp(table[ POSIX Regexp...]) BitmapScanRegexp(table[ POSIX Regexp...])	Forces index scan or index only scan or bitmap scan on the table. Restricts to indexes that matches the specified POSIX regular expression pattern
	NoSeqScan(table)	Forces not to do sequential scan on the table.
	NoTidScan(table)	Forces not to do TID scan on the table.
	NoIndexScan(table)	Forces not to do index scan and index only scan on the table.
	NoIndexOnlyScan(table)	Forces not to do index only scan on the table.
	NoBitmapScan(table)	Forces not to do bitmap scan on the table.
<b>Join method</b>	NestLoop(table table[ table...]) use_nl(table table[ table...])	Forces nested loop for the joins consist of the specified tables.
	HashJoin(table table[ table...]) use_hash(table table[ table...])	Forces hash join for the joins consist of the specified tables.
	MergeJoin(table table[ table...]) use_merge(table table[ table...])	Forces merge join for the joins consist of the specified tables.
	NoNestLoop(table table[ table...]) no_use_nl(table table[ table...])	Forces not to do nested loop for the joins consist of the specified tables.
	NoHashJoin(table table[ table...]) no_use_hash(table table[ table...])	Forces not to do hash join for the joins consist of the specified tables.
	NoMergeJoin(table table[ table...]) no_use_merge(table table[ table...])	Forces not to do merge join for the joins consist of the specified tables.
<b>Join method(oracle mode)</b>	NestLoop(table [ table...]) use_nl(table[ table...])	Forces nested loop for the joins that the specified table is the inner table.
	HashJoin(table[ table...]) use_hash(table[ table...])	Forces hash join for the joins that the specified table is the inner table.
	MergeJoin(table[ table...]) use_merge(table[ table...])	Forces merge join for the joins that the specified table is the inner table.

Group	Format	Description
	NoNestLoop(table[ table...]) no_use_nl(table[ table...])	Forces not to do nested loop for the joins that the specified table is the inner table.
	NoHashJoin(table[ table...]) no_use_hash(table[ table...])	Forces not to do hash join for the joins that the specified table is the inner table.
	NoMergeJoin(table[ table...]) no_use_merge(table[ table...])	Forces not to do merge join for the joins that the specified table is the inner table.
<b>Join order</b>	Leading(table table[ table...]) Ordered(table table[ table...])	Forces join order and directions as specified.
	Leading([join pair]) Ordered([join pair])	Forces join order and directions as specified. A join pair is a pair of tables and/or other join pairs enclosed by parentheses, which can make a nested structure.
	Ordered Leading	Forces to join tables in the order in which they appear in the FROM clause.
	Leading(table) Ordered(table)	Forces to join tables using the specified table as the first table of the join execution plan.
<b>Row number correction</b>	Rows(table [ table...] correction) cardinality(table [ table... ] correction)	Corrects row number of a result of the joins consist of the specified tables or a table or a result of subquery. The available correction methods are absolute (#[n] or [n]), addition (+[n]), subtract (-[n]) and multiplication (*[n]). [n] should be a string that strtod() can read.
<b>Parallel query configuration</b>	Parallel(table [# of workers] [soft hard])	Enforce or inhibit parallel execution of specified table. [# of workers] is the desired number of parallel workers, where zero means inhibiting parallel execution. If the third parameter is soft , it just changes max_parallel_workers_per_gather and leave everything else to planner. Hard(default) means enforcing the specified number of workers.
	Parallel([# of workers] [soft hard])	Enforce or inhibit parallel execution of tables at current query block. [# of workers] is the desired number of parallel workers, where zero means inhibiting parallel execution. If the second parameter is soft , it just changes

Group	Format	Description
		max_parallel_workers_per_gather and leave everything else to planner. Hard(default) means enforcing the specified number of workers.
<b>GUC</b>	Set(GUC-param value)	Set the GUC parameter to the value while planner is running.
	Opt_param('GUC-param' value)	Set the GUC parameter to the value while planner is running.
<b>Query block name</b>	qb_name(name)	Set the query block name, then tables in this query block can be hint in outer query block. can't use for GUC.
<b>No merge</b>	no_merge[(sub query name)] no_merge(@queryblock_name)	Forces not to pull up subquery. Priority is higher than Join method and Join order
<b>Group by method</b>	use_hash_aggregation	Forces hash aggregation method for group by.
	no_use_hash_aggregation	Forces not to use hash method for group by, then use sort method.
<b>Semijoin(specail join)</b>	semijoin	Forces to transforms a correlated EXISTS subquery into a semi-join to access the specified table.
	hash_sj	Forces to transforms a correlated EXISTS subquery into a hash semi-join to access the specified table.
	nl_sj	Forces to transforms a correlated EXISTS subquery into a nestloop semi-join to access the specified table.
	merge_sj	Forces to transforms a correlated EXISTS subquery into a merge semi-join to access the specified table.
	no_semijoin	Forces not to use semi-join if possible, rather than not to pull up sublink
<b>Antijoin(specail join)</b>	hash_aj	Forces to transforms a correlated NOT EXISTS subquery into a hash anti-join to access the specified table.
	nl_aj	Forces to transforms a correlated NOT EXISTS subquery into a nestloop anti-join to access the specified table.
	merge_aj	Forces to transforms a correlated NOT EXISTS

Group	Format	Description
		subquery into a merge anti-join to access the specified table.
<b>Swap_join_inputs</b>	swap_join_input(table)	Forces to use the table as outer table when hashjoin
<b>Ordered predicates</b>	ordered_predicates	Forces the optimizer to preserve the order of predicate evaluation
<b>Unnest</b>	unnest	Pull up sublink is an RBO, so only syntax is supported
<b>No unnest</b>	no_unnest	Forces the optimizer to not pull up sublink
<b>Pq_distribute</b>	pq_distribute(inner_table outer_distribution inner_distribution)	The pq_distribute hint instructs the optimizer how to execute parallel join, inner_table is the inner table of the join, outer_distribution is the distribution for the outer table and inner_distribution is the distribution for the inner table. Now only 'none broadcast' and 'hash hash' is supported, and only 'none broadcast' can work.
<b>No_push_subq</b>	no_push_subq	instructs the optimizer to evaluate nested sublinks as the last step in the execution plan.
<b>Push_subq</b>	push_subq	instructs the optimizer to evaluate nested sublinks at the earliest possible step in the execution plan(it is default in LightDB).
<b>Ignore_row_on_dupkey_index</b>	ignore_row_on_dupkey_index(table indexname) ignore_row_on_dupkey_index(table (colname[, colname...]))	Force to ignore a unique key violation for a specified set of columns or for a specified index.
<b>No_push_pred</b>	no_push_pred[(sub query name)] no_push_pred(@queryblock_name)	Instructs the optimizer not to push a join predicate into the new or subquery.
<b>No_star_transformation</b>	no_star_transformation	Instructs the optimizer not to perform star query transformation.
<b>Append</b>	append	Instructs the optimizer to use direct-path INSERT with the subquery syntax of the INSERT statement.

## F.28. It\_log\_long\_xact

Pl/pgsql function to log long running transactions in LightDB, can optionally output details of any blocking statements and cancel/terminate problematic statements/transactions.

Schedule with cron or similar if required.

Use the cancel/terminate functionality with care, and see notes about better alternatives for some use cases built into lightdb.

## F.28.1. Usage

To simply log long running transactions just call the function passing the shortest duration to start logging at:

```
TEST=# SELECT pg_log_long_xact('1s');
NOTICE: long_xact pid: 4465 duration: 431.325747 ms user:
glyn application: ltsql client: [local] statement: <IDLE> in
transaction
NOTICE: long_xact pid: 16532 duration: 327.438302 ms user: glyn
application: ltsql client: [local] statement: UPDATE balls SET
description = 'TEST' WHERE id = 5;
pg_log_long_xact
-----
(0 rows)
```

To log extra information about locks the long running transactions might be waiting on, supply the second argument as true (although you could log similar information by just enabling `log_lock_waits`):

```
TEST=# SELECT pg_log_long_xact('1s', true);
NOTICE: long_xact pid: 4465 duration: 471.885373 ms user:
glyn application: ltsql client: [local] statement: <IDLE> in
transaction
NOTICE: long_xact pid: 16532 duration: 367.997928 ms user: glyn
application: ltsql client: [local] statement: UPDATE balls SET
description = 'TEST' WHERE id = 5;
NOTICE: long_xact waiter pid: 16532 blocker detail is; pid:
4465 duration: 471.885373 ms relation: any (public.balls
(RowExclusiveLock)) lock type: transaction id 311824482 user:
glyn application: ltsql client: [local] statement: <IDLE> in
transaction
pg_log_long_xact
-----
(0 rows)
```

To set the level of raise used pass a third argument which can be any of “debug”, “log”, “info”, “notice”, “warning” or “text” to output as a text resultset. (in hindsight the default should probably have been “log”)

```
TEST=# \t off
Showing only tuples.
TEST=# SELECT pg_log_long_xact('1s', true, 'text');
long_xact pid: 4465 duration: 574.477076 ms user: glyn
application: ltsql client: [local] statement: <IDLE> in
transaction
long_xact pid: 16532 duration: 470.589631 ms user: glyn
application: ltsql client: [local] statement: UPDATE balls SET
description = 'TEST' WHERE id = 5;
long_xact waiter pid: 16532 blocker detail is; pid: 4465 duration:
574.477076 ms relation: any (public.balls (RowExclusiveLock))
lock type: transaction id 311824482 user: glyn application: ltsql
client: [local] statement: <IDLE> in transaction
```

To make it start cancelling statements exceeding a specific duration we pass a duration as the fourth argument; the first transaction exceeding this will be cancelled on each run, with blocking statements prioritised.

(there's a `lock_timeout` parameter that will abort any statement waiting longer than the specified number of milliseconds, which is much better. Note that the difference here is that this function will attempt to abort the blocking transaction rather than the waiting statement, or if there is no locking just the longest transaction.)

```
TEST=# SELECT pg_log_long_xact('1s', true, 'text', '10 minutes');
 long_xact pid: 4465 duration: 895.57988 ms user: glyn application:
 ltsql client: [local] statement: <IDLE> in transaction
 long_xact unable to cancel backend with pid: 4465
 long_xact pid: 16532 duration: 791.692435 ms user: glyn
 application: ltsql client: [local] statement: UPDATE balls SET
 description = 'TEST' WHERE id = 5;
 long_xact waiter pid: 16532 blocker detail is; pid: 4465 duration:
 895.57988 ms relation: any (public.balls (RowExclusiveLock)) lock
 type: transaction id 31182
4482 user: glyn application: ltsql client: [local] statement:
 <IDLE> in transaction
```

We can also provide a duration as the fifth argument to terminate backends with transactions exceeding this, with prioritisation as per cancelling:

```
TEST=# SELECT pg_log_long_xact('1s', true, 'text', '10 minutes',
 '15 minutes');
 long_xact pid: 4465 duration: 1026.90736 ms user: glyn
 application: ltsql client: [local] statement: <IDLE> in
 transaction
 long_xact terminated backend with pid: 4465
 long_xact pid: 16532 duration: 923.019915 ms user: glyn
 application: ltsql client: [local] statement: UPDATE balls SET
 description = 'TEST' WHERE id = 5;
```

By default the function only cancels/terminates the longest running blocker, or longest running transaction, we can be more forceful than that by passing an extra parameter to tell it to cancel statements/terminate backends of all long running transactions it finds:

```
TEST=# \t off
TEST=# SELECT pg_log_long_xact('1s', true, 'text', '2 minutes', '3
 minutes', true);
 long_xact pid: 19065 duration: 187.279089 ms user: glyn
 application: ltsql client: [local] statement: <IDLE> in
 transaction
 long_xact terminated backend with pid: 19065
 long_xact pid: 16532 duration: 184.251569 ms user: glyn
 application: ltsql client: [local] statement: UPDATE balls SET
 description = 'TEST' WHERE id = 5;
 long_xact cancelled backend with pid: 16532
(4 rows)
```

## F.29. It\_ope

## F.29.1. What is It\_ope?

Order-Preserving Encryption is an encryption method for data preservation order, which allows comparison operations to be directly applied to encrypted data without decrypting operands.

It\_ope support order-preserving encryption for three data types: `bigint`, `double precision`, and `text`. The maximum supported plaintext length of the `text` type is 128 bytes, and the currently supported character types include a total of 128 characters from 0 to 127 in ASCII. The type of ciphertext encrypted by three types of plaintext is `ope_type`.

The ciphertext type `ope_type` supports the following operators: `>`, `>=`, `<`, `<=`, `=` and `!=`. At the same time, the `ope_type` type ciphertext encrypted by the `text` type plaintext supports the like `'xxx %'` operation.

The ciphertext type `ope_type` also supports order `by`, `between...and`, `IN`, `NOT IN` and `BTREE` index.

## F.29.2. function usage

### F.29.2.1. bigint type order-preserving encryption

The `bigint` type encryption interface: `ope_bigint_encrypt(plaintext bigint) return ope_type`.

```
SELECT ope_bigint_encrypt(12345678);
           ope_bigint_encrypt
-----
663667376838DD03DDFF2F57DE01DE028841DF02DF43DF63DF65DF68
```

### F.29.2.2. double precision type order-preserving encryption

The `double precision` type encryption interface: `ope_double_encrypt(plaintext double precision) return ope_type`.

```
SELECT ope_double_encrypt(1234.5678);
           ope_double_encrypt
-----
663667376838DC02DDFF5227DE01DE026961DF02DDF4DF43DF63DF65DF68DDFDDDFDDDFDDDFDDDD
```

### F.29.2.3. text type order-preserving encryption

The `text` type encryption interface: `ope_text_encrypt(plaintext text) return ope_type`.

```
SELECT ope_text_encrypt('123456789@qq.com');
           ope_text_encrypt
-----
6535643463336232DDFF52CBDE01DE02FD63DF02DF43DF63DF65DF68DF6CDFE2FF82FF82DDF4FD
```

### F.29.2.4. OPE decryption

The OPE decryption interface: `ope_decrypt(ciphertext ope_type) return text`.

## F.29.2.5. OPE example

The following is an example of order-preserving encryption of text type:

```
-- The info field in the test_ope table is plaintext of text type,
-- and the opedata field is order-preserving encrypted ciphertext of
-- type ope_type:
create table test_ope(id int, info text, opedata ope_type, crt_time
timestamp not null);
CREATE TABLE
```

```
create index opedata_index on test_ope USING BTREE (opedata);
CREATE INDEX
```

```
select * from test_ope ;
      id | info
```

```
| opedata
```

```
| crt_time
```

```

```

## F.30. lt\_pathman

The `lt_pathman` module provides optimized partitioning mechanism and functions to manage partitions.

### F.30.1. Overview

**Partitioning** means splitting one large table into smaller pieces. Each row in such table is moved to a single partition according to the partitioning key.

LightDB provides native partitioning:

```
CREATE TABLE test(id int4, value text) PARTITION BY RANGE(id);
CREATE TABLE test_1 PARTITION OF test FOR VALUES FROM (1) TO (10);
CREATE TABLE test_2 PARTITION OF test FOR VALUES FROM (10) TO (20);
```

It's not so different from the classic approach; there are implicit check constraints, and most of its limitations are still relevant.

Despite the flexibility, this approach forces the planner to perform an exhaustive search and to check constraints on each partition to determine whether it should be present in the plan or not. Large amount of partitions may result in significant planning overhead.

The `lt_pathman` module features partition managing functions and optimized planning mechanism which utilizes knowledge of the partitions' structure. It stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization stage the `lt_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a `SELECT` query is executed, `lt_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are `=`, `<`, `<=`, `>`, `>=`), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `lt_pathman` searches for the corresponding partitions and builds the plan. Currently `lt_pathman` supports two partitioning schemes:

- **RANGE** - maps rows to partitions using partitioning key ranges assigned to each partition. Optimization is achieved by using the binary search algorithm;
- **HASH** - maps rows to partitions using a generic hash function.

More interesting features are yet to come. Stay tuned!

### F.30.2. Feature highlights

- HASH and RANGE partitioning schemes;

- Partitioning by expression and composite key;
- Both automatic and manual partition management;
- Support for integer, floating point, date and other types, including domains;
- Effective query planning for partitioned tables (JOINS, subselects etc);
- RuntimeAppend & RuntimeMergeAppend custom plan nodes to pick partitions at runtime;
- PartitionFilter: an efficient drop-in replacement for INSERT triggers;
- PartitionRouter and PartitionOverseer for cross-partition UPDATE queries (instead of triggers);
- Automatic partition creation for new INSERTed data (only for RANGE partitioning);
- Improved COPY FROM statement that is able to insert rows directly into partitions;
- User-defined callbacks for partition creation event handling;
- Non-blocking concurrent table partitioning;
- FDW support (foreign partitions);
- Various GUC toggles and configurable settings.
- Partial support of declarative partitioning.

## F.30.3. Available functions

### F.30.3.1. Module's version

```
pathman_version()
```

This function returns a complete version number of the loaded `lt_pathman` module in MAJOR.MINOR.PATCH format.

### F.30.3.2. Partition creation

```
create_hash_partitions(parent_relid    REGCLASS,  
                       expression     TEXT,  
                       partitions_count INTEGER,  
                       partition_data  BOOLEAN DEFAULT TRUE,  
                       partition_names TEXT[] DEFAULT NULL,  
                       tablespaces    TEXT[] DEFAULT NULL)
```

Performs HASH partitioning for relation by partitioning expression `expr`. The `partitions_count` parameter specifies the number of partitions to create; it cannot be changed afterwards. If `partition_data` is true then all the data will be automatically copied from the parent table to partitions. Note that data migration may took a while to finish and the table will be locked until transaction commits. See `partition_table_concurrently()` for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see `set_init_callback()`).

```
create_range_partitions(parent_relid    REGCLASS,  
                       expression     TEXT,  
                       start_value     ANYELEMENT,  
                       p_interval     ANYELEMENT,  
                       p_count        INTEGER DEFAULT NULL,  
                       partition_data  BOOLEAN DEFAULT TRUE)
```

```
create_range_partitions(parent_relid    REGCLASS,  
                       expression     TEXT,  
                       start_value     ANYELEMENT,  
                       p_interval     INTERVAL,  
                       p_count        INTEGER DEFAULT NULL,
```

```

                                partition_data  BOOLEAN DEFAULT TRUE)

create_range_partitions(parent_relid  REGCLASS,
                       expression    TEXT,
                       bounds        ANYARRAY,
                       partition_names TEXT[] DEFAULT NULL,
                       tablespaces    TEXT[] DEFAULT NULL,
                       partition_data BOOLEAN DEFAULT TRUE)

```

Performs RANGE partitioning for relation by partitioning expression `expr`, `start_value` argument specifies initial value, `p_interval` sets the default range for auto created partitions or partitions created with `append_range_partition()` or `prepend_range_partition()` (if NULL then auto partition creation feature won't work), `p_count` is the number of pre-made partitions (if not set then `lt_pathman` tries to determine it based on expression's values). The bounds array can be built using `generate_range_bounds()`. Partition creation callback is invoked for each partition if set beforehand.

```

generate_range_bounds(p_start  ANYELEMENT,
                     p_interval INTERVAL,
                     p_count   INTEGER)

```

```

generate_range_bounds(p_start  ANYELEMENT,
                     p_interval ANYELEMENT,
                     p_count   INTEGER)

```

Builds bounds array for `create_range_partitions()`.

### F.30.3.3. Data migration

```

partition_table_concurrently(relation  REGCLASS,
                             batch_size INTEGER DEFAULT 1000,
                             sleep_time FLOAT8 DEFAULT 1.0)

```

Starts a background worker to move data from parent table to partitions. The worker utilizes short transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly interfere with user's activity. If the worker is unable to lock rows of a batch, it sleeps for `sleep_time` seconds before the next attempt and tries again up to 60 times, and quits if it's still unable to lock the batch.

```

stop_concurrent_part_task(relation REGCLASS)

```

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it finishes relocating a current batch.

### F.30.3.4. Triggers

Triggers are no longer required nor for INSERTs, neither for cross-partition UPDATES. However, user-supplied triggers *are supported*:

- Each **inserted row** results in execution of BEFORE/AFTER INSERT trigger functions of a *corresponding partition*.
- Each **updated row** results in execution of BEFORE/AFTER UPDATE trigger functions of a *corresponding partition*.
- Each **moved row** (cross-partition update) results in execution of BEFORE UPDATE + BEFORE/AFTER DELETE + BEFORE/AFTER INSERT trigger functions of *corresponding partitions*.

### F.30.3.5. Post-creation partition management

```
replace_hash_partition(old_partition REGCLASS,  
                      new_partition REGCLASS,  
                      lock_parent   BOOLEAN DEFAULT TRUE)
```

Replaces specified partition of HASH-partitioned table with another table. The `lock_parent` parameter will prevent any INSERT/UPDATE/ALTER TABLE queries to parent table.

```
split_range_partition(partition_relid REGCLASS,  
                    split_value      ANYELEMENT,  
                    partition_name   TEXT DEFAULT NULL,  
                    tablespace      TEXT DEFAULT NULL)
```

Split RANGE partition in two by `split_value`. Partition creation callback is invoked for a new partition if available.

```
merge_range_partitions(variadic partitions REGCLASS[])
```

Merge several adjacent RANGE partitions. Partitions are automatically ordered by increasing bounds; all the data will be accumulated in the first partition.

```
append_range_partition(parent_relid   REGCLASS,  
                      partition_name TEXT DEFAULT NULL,  
                      tablespace     TEXT DEFAULT NULL)
```

Append new RANGE partition with `pathman_config.range_interval` as interval.

```
prepend_range_partition(parent_relid   REGCLASS,  
                      partition_name TEXT DEFAULT NULL,  
                      tablespace     TEXT DEFAULT NULL)
```

Prepend new RANGE partition with `pathman_config.range_interval` as interval.

```
add_range_partition(parent_relid   REGCLASS,  
                   start_value    ANYELEMENT,  
                   end_value      ANYELEMENT,  
                   partition_name TEXT DEFAULT NULL,  
                   tablespace     TEXT DEFAULT NULL)
```

Create new RANGE partition for relation with specified range bounds. If `start_value` or `end_value` are NULL then corresponding range bound will be infinite.

```
drop_range_partition(partition TEXT, delete_data BOOLEAN DEFAULT  
                    TRUE)
```

Drop RANGE partition and all of its data if `delete_data` is true.

```
attach_range_partition(parent_relid   REGCLASS,  
                      partition_relid REGCLASS,  
                      start_value    ANYELEMENT,  
                      end_value      ANYELEMENT)
```

Attach partition to the existing RANGE-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if set (see `pathman_config_params`).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing RANGE-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable `lt_pathman` partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS,  
                delete_data BOOLEAN DEFAULT FALSE)
```

Drop partitions of the `parent` table (both foreign and local relations). If `delete_data` is `false`, the data is copied to the parent table first. Default is `false`.

To remove partitioned table along with all partitions fully, use conventional `DROP TABLE relation CASCADE`. However, care should be taken in somewhat rare case when you are running logical replication and `DROP` was executed by replication apply worker, e.g. via trigger on replicated table. `lt_pathman` uses `pathman_ddl_trigger` event trigger to remove the record about dropped table from `pathman_config`, and this trigger by default won't fire on replica, leading to inconsistent state when `lt_pathman` thinks that the table still exists, but in fact it doesn't. If this is the case, configure this trigger to fire on replica too:

```
ALTER EVENT TRIGGER pathman_ddl_trigger ENABLE ALWAYS;
```

Physical replication doesn't have this problem since DDL as well as `pathman_config` table is replicated too; master and slave LightDB instances are basically identical, and it is only harmful to keep this trigger in `ALWAYS` mode.

### F.30.3.6. Additional parameters

```
set_interval(relation REGCLASS, value ANYELEMENT)
```

Update RANGE partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for `TIMESTAMP` and at least 1 day for `DATE`.

```
set_enable_parent(relation REGCLASS, value BOOLEAN)
```

Include/exclude parent table into/from query plan. In original LightDB planner parent table is always included into query plan even if it's empty which can lead to additional overhead. You can use `disable_parent()` if you are never going to use parent table as a storage. Default value depends on the `partition_data` parameter that was specified during initial partitioning in `create_range_partitions()` function. If the `partition_data` parameter was `true` then all data have already been migrated to partitions and parent table disabled. Otherwise it is enabled.

```
set_auto(relation REGCLASS, value BOOLEAN)
```

Enable/disable auto partition propagation (only for RANGE partitioning). It is enabled by default.

```
set_init_callback(relation REGCLASS, callback REGPROC DEFAULT 0)
```

Set partition creation callback to be invoked for each attached or created partition (both HASH and RANGE). If callback is marked with SECURITY INVOKER, it's executed with the privileges of the user that produced a statement which has led to creation of a new partition (e.g. INSERT INTO partitioned\_table VALUES (-5)). The callback must have the following signature: part\_init\_callback(args JSONB) RETURNS VOID. Parameter arg consists of several fields whose presence depends on partitioning type:

```
/* RANGE-partitioned table abc (child abc_4) */
{
  "parent":          "abc",
  "parent_schema":  "public",
  "parttype":        "2",
  "partition":       "abc_4",
  "partition_schema": "public",
  "range_max":       "401",
  "range_min":       "301"
}

/* HASH-partitioned table abc (child abc_0) */
{
  "parent":          "abc",
  "parent_schema":  "public",
  "parttype":        "1",
  "partition":       "abc_0",
  "partition_schema": "public"
}
```

```
set_set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)
```

When INSERTing new data beyond the partitioning range, use SpawnPartitionsWorker to create new partitions in a separate transaction.

## F.30.4. Views and tables

### F.30.4.1. pathman\_config — main config storage

```
CREATE TABLE IF NOT EXISTS pathman_config (
  partrel          REGCLASS NOT NULL PRIMARY KEY,
  expr             TEXT NOT NULL,
  parttype         INTEGER NOT NULL,
  range_interval   TEXT,
  cooked_expr      TEXT);
```

This table stores a list of partitioned tables.

### F.30.4.2. pathman\_config\_params — optional parameters

```
CREATE TABLE IF NOT EXISTS pathman_config_params (
  partrel          REGCLASS NOT NULL PRIMARY KEY,
  enable_parent    BOOLEAN NOT NULL DEFAULT TRUE,
  auto             BOOLEAN NOT NULL DEFAULT TRUE,
```

```
init_callback    TEXT DEFAULT NULL,  
spawn_using_bgw BOOLEAN NOT NULL DEFAULT FALSE);
```

This table stores optional parameters which override standard behavior.

### F.30.4.3. `pathman_concurrent_part_tasks` — currently running partitioning workers

```
-- helper SRF function  
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()  
RETURNS TABLE (  
    userid      REGROLE,  
    pid         INT,  
    dbid        OID,  
    relid       REGCLASS,  
    processed   INT,  
    status      TEXT)  
AS 'lt_pathman', 'show_concurrent_part_tasks_internal'  
LANGUAGE C STRICT;  
  
CREATE OR REPLACE VIEW pathman_concurrent_part_tasks  
AS SELECT * FROM show_concurrent_part_tasks();
```

This view lists all currently running concurrent partitioning tasks.

### F.30.4.4. `pathman_partition_list` — list of all existing partitions

```
-- helper SRF function  
CREATE OR REPLACE FUNCTION show_partition_list()  
RETURNS TABLE (  
    parent      REGCLASS,  
    partition   REGCLASS,  
    parttype    INT4,  
    expr        TEXT,  
    range_min   TEXT,  
    range_max   TEXT)  
AS 'lt_pathman', 'show_partition_list_internal'  
LANGUAGE C STRICT;  
  
CREATE OR REPLACE VIEW pathman_partition_list  
AS SELECT * FROM show_partition_list();
```

This view lists all existing partitions, as well as their parents and range boundaries (NULL for HASH partitions).

### F.30.4.5. `pathman_cache_stats` — per-backend memory consumption

```
-- helper SRF function  
CREATE OR REPLACE FUNCTION @extschema@.show_cache_stats()  
RETURNS TABLE (  
    context     TEXT,  
    size        INT8,
```

```

        used          INT8,
        entries       INT8)
AS 'lt_pathman', 'show_cache_stats_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW @extschema@.pathman_cache_stats
AS SELECT * FROM @extschema@.show_cache_stats();

```

Shows memory consumption of various caches.

## F.30.5. Declarative partitioning

ATTACH PARTITION, DETACH PARTITION and CREATE TABLE .. PARTITION OF commands could be used with tables partitioned by `lt_pathman`:

```

CREATE TABLE child1 (LIKE partitioned_table);

--- attach new partition
ALTER TABLE partitioned_table ATTACH PARTITION child1
    FOR VALUES FROM ('2015-05-01') TO ('2015-06-01');

--- detach the partition
ALTER TABLE partitioned_table DETACH PARTITION child1;

-- create a partition
CREATE TABLE child2 PARTITION OF partitioned_table
    FOR VALUES IN ('2015-05-01', '2015-06-01');

```

## F.30.6. Custom plan nodes

`lt_pathman` provides a couple of custom plan nodes<sup>3</sup> which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for `INSERT` triggers)
- `PartitionOverseer` (implements cross-partition `UPDATES`)
- `PartitionRouter` (implements cross-partition `UPDATES`)

`PartitionFilter` acts as a *proxy node* for `INSERT`'s child scan, which means it can redirect output tuples to the corresponding partition:

```

EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
SELECT generate_series(1, 10), random();
      QUERY PLAN
-----
Insert on partitioned_table
-> Custom Scan (PartitionFilter)
    -> Subquery Scan on "*SELECT*"
        -> Result

(4 rows)

```

`PartitionOverseer` and `PartitionRouter` are another *proxy nodes* used in conjunction with `PartitionFilter` to enable cross-partition `UPDATES` (i.e. when update of partitioning key

<sup>3</sup> <https://wiki.postgresql.org/wiki/CustomScanAPI>

requires that we move row to another partition). Since this node has a great deal of side effects (ordinary UPDATE becomes slower; cross-partition UPDATE is transformed into DELETE + INSERT), it is disabled by default. To enable it, refer to the list of GUCs below.

```
EXPLAIN (COSTS OFF)
UPDATE partitioned_table
SET value = value + 1 WHERE value = 2;
          QUERY PLAN
-----
Custom Scan (PartitionOverseer)
  -> Update on partitioned_table_2
      -> Custom Scan (PartitionFilter)
          -> Custom Scan (PartitionRouter)
              -> Seq Scan on partitioned_table_2
                  Filter: (value = 2)

(6 rows)
```

RuntimeAppend and RuntimeMergeAppend have much in common: they come in handy in a case when WHERE condition takes form of:

```
VARIABLE OP PARAM
```

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the *WHERE condition analysis routine* into the original Append's code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```
/* create table we're going to partition */
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);

/* insert some data */
INSERT INTO partitioned_table
SELECT generate_series(1, 1000), random();

/* perform partitioning */
SELECT create_hash_partitions('partitioned_table', 'id', 100);

/* create ordinary table */
CREATE TABLE some_table AS SELECT generate_series(1, 100) AS VAL;

• id = (select ... limit 1)
```

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
          QUERY PLAN
-----
Custom Scan (RuntimeAppend) (actual time=0.030..0.033 rows=1
loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.011..0.011 rows=1 loops=1)
        -> Seq Scan on some_table (actual time=0.010..0.010
rows=1 loops=1)
```

```

-> Seq Scan on partitioned_table_70 partitioned_table (actual
time=0.004..0.006 rows=1 loops=1)
    Filter: (id = $0)
    Rows Removed by Filter: 9
Planning time: 1.131 ms
Execution time: 0.075 ms
(9 rows)

```

```

/* disable RuntimeAppend node */
SET lt_pathman.enable_runtimeappend = f;

```

```

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
                QUERY PLAN
-----

```

```

Append (actual time=0.196..0.274 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.005..0.005 rows=1 loops=1)
        -> Seq Scan on some_table (actual time=0.003..0.003
rows=1 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.014..0.014
rows=0 loops=1)
        Filter: (id = $0)
        Rows Removed by Filter: 6
    -> Seq Scan on partitioned_table_1 (actual time=0.003..0.003
rows=0 loops=1)
        Filter: (id = $0)
        Rows Removed by Filter: 5
    ... /* more plans follow */
Planning time: 1.140 ms
Execution time: 0.855 ms
(306 rows)

```

• **id = ANY (select ...)**

```

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);
                QUERY PLAN
-----

```

```

Nested Loop (actual time=0.025..0.060 rows=4 loops=1)
  -> Limit (actual time=0.009..0.011 rows=4 loops=1)
      -> Seq Scan on some_table (actual time=0.008..0.010
rows=4 loops=1)
  -> Custom Scan (RuntimeAppend) (actual time=0.002..0.004 rows=1
loops=4)
      -> Seq Scan on partitioned_table_70 partitioned_table
(actual time=0.001..0.001 rows=10 loops=1)
      -> Seq Scan on partitioned_table_26 partitioned_table
(actual time=0.002..0.003 rows=9 loops=1)
      -> Seq Scan on partitioned_table_27 partitioned_table
(actual time=0.001..0.002 rows=20 loops=1)
      -> Seq Scan on partitioned_table_63 partitioned_table
(actual time=0.001..0.002 rows=9 loops=1)
Planning time: 0.771 ms
Execution time: 0.101 ms
(10 rows)

```

```

/* disable RuntimeAppend node */
SET lt_pathman.enable_runtimeappend = f;

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);
                                QUERY PLAN
-----
Nested Loop Semi Join (actual time=0.531..1.526 rows=4 loops=1)
  Join Filter: (partitioned_table.id = some_table.val)
  Rows Removed by Join Filter: 3990
  -> Append (actual time=0.190..0.470 rows=1000 loops=1)
    -> Seq Scan on partitioned_table (actual
time=0.187..0.187 rows=0 loops=1)
    -> Seq Scan on partitioned_table_0 (actual
time=0.002..0.004 rows=6 loops=1)
    -> Seq Scan on partitioned_table_1 (actual
time=0.001..0.001 rows=5 loops=1)
    -> Seq Scan on partitioned_table_2 (actual
time=0.002..0.004 rows=14 loops=1)
... /* 96 scans follow */
  -> Materialize (actual time=0.000..0.000 rows=4 loops=1000)
    -> Limit (actual time=0.005..0.006 rows=4 loops=1)
      -> Seq Scan on some_table (actual time=0.003..0.004
rows=4 loops=1)
Planning time: 2.169 ms
Execution time: 2.059 ms
(110 rows)

```

- **NestLoop involving a partitioned table**, which is omitted since it's occasionally shown above.

## F.30.7. Examples

### F.30.7.1. Common tips

- You can easily add *partition* column containing the names of the underlying partitions using the system attribute called *tableoid*:

```
SELECT tableoid::regclass AS partition, * FROM partitioned_table;
```

- Though indices on a parent table aren't particularly useful (since it's supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, *lt\_pathman* will create a similar index on every partition.
- All running concurrent partitioning tasks can be listed using the *pathman\_concurrent\_part\_tasks* view:

```

SELECT * FROM pathman_concurrent_part_tasks;
userid | pid  | dbid  | relid | processed | status
-----+-----+-----+-----+-----+-----
dmitry | 7367 | 16384 | test  | 472000    | working
(1 row)

```

- *pathman\_partition\_list* in conjunction with *drop\_range\_partition()* can be used to drop RANGE partitions in a more flexible way compared to good old DROP TABLE:

```

SELECT drop_range_partition(partition, false) /* move data to
parent */
FROM pathman_partition_list
WHERE parent = 'part_test'::regclass AND range_min::int < 500;
NOTICE:  1 rows copied from part_test_11
NOTICE:  100 rows copied from part_test_1
NOTICE:  100 rows copied from part_test_2
drop_range_partition
-----
dummy_test_11
dummy_test_1
dummy_test_2
(3 rows)

```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into parent will be redirected to foreign partitions (as usual, `PartitionFilter` will be involved), though by default it is prohibited to insert rows into partitions provided not by `postgres_fdw`. Only superuser is allowed to set `lt_pathman.insert_into_fdw` GUC variable.

## F.30.7.2. HASH partitioning

Consider an example of HASH partitioning. First create a table with some integer column:

```

CREATE TABLE items (
    id          SERIAL PRIMARY KEY,
    name       TEXT,
    code       BIGINT);

INSERT INTO items (id, name, code)
SELECT g, md5(g::text), random() * 100000
FROM generate_series(1, 100000) as g;

```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from parent to partitions.

Here's an example of the query performing filtering by partitioning key:

```

SELECT * FROM items WHERE id = 1234;
 id | name | code
-----+-----+-----
 1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855
(1 row)

```

```

EXPLAIN SELECT * FROM items WHERE id = 1234;
                    QUERY PLAN
-----
Append  (cost=0.28..8.29 rows=0 width=0)
->  Index Scan using items_34_pkey on items_34  (cost=0.28..8.29
rows=0 width=0)
      Index Cond: (id = 1234)

```

Notice that the `Append` node contains only one child scan which corresponds to the `WHERE` clause.

**Important:** pay attention to the fact that `lt_pathman` excludes the parent table from the query plan.

To access parent table use `ONLY` modifier:

```
EXPLAIN SELECT * FROM ONLY items;
          QUERY PLAN
-----
Seq Scan on items (cost=0.00..0.00 rows=1 width=45)
```

### F.30.7.3. RANGE partitioning

Consider an example of RANGE partitioning. Let's create a table containing some dummy logs:

```
CREATE TABLE journal (
    id      SERIAL,
    dt      TIMESTAMP NOT NULL,
    level   INTEGER,
    msg     TEXT);

-- similar index will also be created for each partition
CREATE INDEX ON journal(dt);

-- generate some data
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1
minute') as g;
```

Run the `create_range_partitions()` function to create partitions so that each partition would contain the data for one day:

```
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date,
'1 day'::interval);
```

It will create 365 partitions and move the data from parent to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

```
-- add new partition with specified range
SELECT add_range_partition('journal', '2016-01-01'::date,
'2016-01-07'::date);

-- append new partition with default range
SELECT append_range_partition('journal');
```

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```
CREATE FOREIGN TABLE journal_archive (
    id      INTEGER NOT NULL,
    dt      TIMESTAMP NOT NULL,
    level   INTEGER,
```

```

msg      TEXT)
SERVER archive_server;

SELECT attach_range_partition('journal', 'journal_archive',
    '2014-01-01'::date, '2015-01-01'::date);

```

**Important:** the definition of the attached table must match the one of the existing partitioned table, including the dropped columns.

To merge to adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here's an example of the query performing filtering by partitioning key:

```

SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt <
    '2015-06-03';

```

id	dt	level	msg
217441	2015-06-01 00:00:00	2	15053892d993ce19f580a128f87e3dbf
217442	2015-06-01 00:01:00	1	3a7c46f18a952d62ce5418ac2056010c
217443	2015-06-01 00:02:00	0	92c8de8f82faf0b139a3d99f2792311d
...			

(2880 rows)

```

EXPLAIN SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt <
    '2015-06-03';

```

QUERY PLAN

```

-----
Append (cost=0.00..58.80 rows=0 width=0)
-> Seq Scan on journal_152 (cost=0.00..29.40 rows=0 width=0)
-> Seq Scan on journal_153 (cost=0.00..29.40 rows=0 width=0)
(3 rows)

```

### F.30.7.4. Disabling `lt_pathman`

There are several user-accessible GUC variables designed to toggle the whole module or specific custom nodes on and off:

- `lt_pathman.enable` — disable (or enable) `lt_pathman` **completely**
- `lt_pathman.enable_runtimeappend` — toggle `RuntimeAppend` custom node on
- `lt_pathman.enable_runtimemergeappend` — toggle `RuntimeMergeAppend` custom node on
- `lt_pathman.enable_partitionfilter` — toggle `PartitionFilter` custom node on(for INSERTs)

- `lt_pathman.enable_partitionrouter` — toggle PartitionRouter custom node on(for cross-partition UPDATES)
- `lt_pathman.enable_auto_partition` — toggle automatic partition creation on(per session)
- `lt_pathman.enable_bounds_cache` — toggle bounds cache on(faster updates of partitioning scheme)
- `lt_pathman.insert_into_fdw` — allow INSERTs into various FDWs (`disabled | postgres | any_fdw`)
- `lt_pathman.override_copy` — toggle COPY statement hooking on

To **permanently** disable `lt_pathman` for some previously partitioned table, use the `disable_pathman_for()` function:

```
SELECT disable_pathman_for('range_rel');
```

All sections and data will remain unchanged and will be handled by the standard LightDB inheritance mechanism.

## F.31. lt\_patch

The `lt_patch` module provides a means for tracking the information of all patches executed by a server.

Before creating `lt_patch` you must first create `file_fdw` extension and set `LTHOME` environment variable.

When `lt_patch` is loaded, it tracks patches across all databases of the server. To access and manipulate these patch information, the module provides a table, `lt_patch`, and the utility functions `lt_patch`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION lt_patch`.

### F.31.1. The lt\_patch table

The information gathered by the module are made available via a table named `lt_patch`. This table contains one row for each distinct path. The columns of the table are shown in Table F.15.

**Table F.15. lt\_patch Columns**

Column	Type	Description
<code>name</code>	<code>varchar</code>	patch name
<code>dependency</code>	<code>varchar</code>	dependency patch
<code>component_type</code>	<code>varchar</code>	component type : PATCH BUGFIX
<code>apply_type</code>	<code>varchar</code>	apply type : INSTANCE APP BOTH
<code>apply_version</code>	<code>varchar</code>	apply version
<code>action</code>	<code>varchar</code>	action : REMOVED INSTALLED
<code>status</code>	<code>varchar</code>	status : "APP FAILED" "APP SUCCESS" "INSTANCE FAILED" "SUCCESS"

Column Type	Description
create_time timestamp	patch create time
update_time timestamp	patch update time

## F.31.2. Functions

`lt_patch(showtext boolean)` returns setof record

The `lt_patch` table is defined in terms of a function also named `lt_patch`.

## F.31.3. Sample Output

```
lightdb@postgres=# select * from lt_patch;
   name      | dependency | component_type | apply_type |
apply_version | action    | status  | create_time |
update_time
-----+-----+-----+-----+-----
patch-1.0-8717 |          | patch      | BOTH      |
| 13.8-22.4   | removed  |          | 2022-12-29 18:25:48 |
2022-12-29 19:24:33
1.0-8719      |          | patch      | BOTH      |
| 13.8-22.4   | removed  |          | 2022-12-29 19:58:39 |
2022-12-29 21:18:52
(2 rows)
```

```
lightdb@postgres=# select lt_patch();
                                lt_patch
-----+-----+-----+-----+-----
(patch-1.0-8717,,patch,BOTH,13.8-22.4,removed,, "2022-12-29
18:25:48", "2022-12-29 19:24:33")
(1.0-8719,,patch,BOTH,13.8-22.4,removed,, "2022-12-29
19:58:39", "2022-12-29 21:18:52")
(2 rows)
```

## F.32. lt\_prewarm

The `lt_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the LightDB buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `lt_prewarm` in `shared_preload_libraries`. In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

Lightdb adds the function of automatic prewarming during startup (restart), including automatically prewarming the database, tables and indexes. When prewarming the database, it will prewarms all non system tables under the database (including partition tables and indexes under the table). When prewarming the table alone, it will also prewarms the partition tables and indexes of the table. Of course, when configuring the prewarming database and the tables under the database at the same time, we will not repeat the prewarming.

## F.32.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default
'main',
           first_block int8 default null,
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by LightDB when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

## F.32.2. Configuration Parameters

```
lt_prewarm.autoprewarm (boolean)
```

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

```
lt_prewarm.autoprewarm_interval (int)
```

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in `lightdb.conf`. Typical usage might be:

```
# lightdb.conf
shared_preload_libraries = 'pg_prewarm'

pg_prewarm.autoprewarm = true
```

```
pg_prewarm.autoprewarm_interval = 300s
```

```
lt_prewarm.lt_autoprewarm_dbs (text)
```

This parameter configures the list of databases to be prewarmed automatically. for example, `lt_prewarm.lt_autoprewarm_dbs = 'db1, db2, db3'`.

```
lt_prewarm.lt_autoprewarm_tables (text)
```

This parameter configures the list of tables to be prewarmed automatically. for example, `lt_prewarm.lt_autoprewarm_tables = 'db1.schema1.t1, db1.schema1.t2, db1.schema2.t1, db2.schema1.t1'`.

```
lt_prewarm.lt_autoprewarm_indexes (text)
```

This parameter configures the list of indexes to be prewarmed automatically. for example, `lt_prewarm.lt_autoprewarm_indexes = 'db1.schema1.i1, db1.schema1.i2, db1.schema2.i1, db2.schema1.i1'`.

### F.32.3. Author

Robert Haas <rhaas@postgresql.org>

## F.33. It\_proctab

`lt_proctab` is a collection of stored functions that can access the operating systems process table so that system statistics can be queried through the database.

### F.33.1. functions

#### F.33.1.1. pg\_proctab

Gets information about all LightDB processes. The list of all processes is retrieved from `pg_stat_activity`, and process information is retrieved from the `/proc` system file.

```
lightdb@postgres=# select * from pg_proctab();
-[ RECORD 1 ]-----+-----
pid           | 64994
comm          | lightdb
fullcomm      | lightdb: autovacuum launcher
state         | S
ppid          | 64986
pgrp          | 64994
session       | 64994
tty_nr        | 0
tpgid         | -1
flags         | 4202560
minflt        | 529
cminflt       | 0
majflt        | 0
cmajflt       | 0
utime         | 1
stime         | 0
cutime        | 0
cstime        | 0
priority      | 20
nice          | 0
```

num_threads		1
itrealvalue		0
starttime		3258371
vsize		1902161920
rss		3588
exit_signal		17
processor		3
rt_priority		0

reads		0
writes		0
cwrites		0

### F.33.1.2. pg\_cputime

CPU information obtained from /proc/stat.

```
lightdb@postgres=# select * from pg_cputime();
 user | nice | system | idle | iowait
-----+-----+-----+-----+-----
 289580 | 61 | 29378 | 15540161 | 7253
(1 row)
```

### F.33.1.3. pg\_loadavg

Load information obtained from /proc/loadavg.

```
lightdb@postgres=# select * from pg_loadavg();
 load1 | load5 | load15 | last_pid
-----+-----+-----+-----
 0.08 | 0.05 | 0.05 | 74363
(1 row)
```

### F.33.1.4. pg\_loadavg

Memory usage information obtained from /proc/meminfo.

```
lightdb@postgres=# select * from pg_memusage();
 memused | memfree | memshared | membuffers | memcached | swapused
 | swapfree | swapcached
-----+-----+-----+-----+-----+-----

writetime      | 351385
current_io     | 0
iotime         | 326759
totaliotime    | 372183
```

## F.34. It\_profile

This extension for LightDB helps you to find out most resource-consuming activities in your LightDB databases.

### F.34.1. Concepts

Extension is based on statistic views of LightDB and contrib extension *lt\_stat\_statements*, *lt\_stat\_activity* and *system\_stats*. It is written in pure pl/pgsql and doesn't need any external libraries or software, but LightDB database itself.

Historic repository will be created in your database by this extension. This repository will hold statistic "samples" for your lightdb clusters. Sample is taken by calling *take\_sample()* function. LightDB also provide another *lt\_cron* extension tool performing periodic take sample tasks.

Periodic samples can help you finding most resource intensive activities in the past. Suppose, you were reported performance degradation several hours ago. Resolving such issue, you can build a report between two samples bounding performance issue period to see load profile of your database.

You can take an explicit sample before running any batch processing, and after it will be done.

Any time you are taking a sample, *pg\_stat\_statements\_reset()* will be called, ensuring you wont loose statements due to reaching *lt\_stat\_statements.max*. Also, report will contain section, informing you if captured statements count in any sample reaches 90% of *lt\_stat\_statements.max*.

*lt\_profile*, installed in one cluster is able to collect statistics from other clusters, called *servers*. You just need to define some servers, providing names and connection strings and make sure connection can be established to all databases of all *servers*. Now you can track, for example, statistics on your standbys from master, or from any other server. Once extension is installed, a *local* server is automatically created - this is a server for cluster where *lt\_profile* resides.

### F.34.2. Extension architecture

Extension consists of four parts:

- **Historic repository** is a storage for sampling data. Repository is a set of extension tables.
- **Sample management engine** is a set of functions, used for taking *samples* and support repository by removing obsolete sample data from it.

- **Report engine** is a set of functions used for report generation based on data from historic repository.
- **Administrative functions** allows you to create and manage *servers* and *baselines*.

## F.34.2.1. Extension tables

### F.34.2.1.1. servers

Monitored servers (LightDB clusters) list.

**Table F.16. servers Columns**

Column Type	Description
server_id integer	Server id
server_name name	Server name
server_description text	Server description
server_created timestamp with time zone DEFAULT	Server created timestamp, default now()
db_exclude name[ ]	Databases that should be excluded
enabled boolean	Enabled or not, default true
connstr text	Connstr for dblink
max_sample_age integer	Global setting of max_sample_age would be overridden by this value if set
last_sample_id integer	Last sample id, default 0
size_smp_wnd_start time with time zone	Sample window start timestamp
size_smp_wnd_dur interval hour to second	Sample window duration
size_smp_interval interval day to minute	Sample window interval

### F.34.2.1.2. samples

Sample times list.

**Table F.17. samples Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
sample_time timestamp (0) with time zone	Timestamp of this sample

### F.34.2.1.3. sample\_server\_hardware

Server hardware information (collected by system\_stats). The information includes the number of CPUs, threads, cores, sockets, memory, etc.

**Table F.18. sample\_server\_hardware Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
architecture text	Cpu architecture of the system
byte_order text	Byte order of the architecture
cpus integer	Cpu count
threads_per_core integer	Thread count per core
cores_per_socket integer	Core count per socket
sockets integer	Sockets of the system
vendor_id text	Vendor id
cpu_family integer	Cpu family
model integer	Model of the system
model_name text	Model name of the system
cpu_mhz text	Cpu frequency in mhz
l1dcache text	Level 1 data cache
l1icache text	Level 1 instruction cache
l2cache text	Level 2 cache
l3cache t	Level 3 cache
memory_total integer	Memory in total
swap_total integer	Swap memory in total

### F.34.2.1.4. sample\_cluster\_instance

Cluster configuration information.

**Table F.19. sample\_cluster\_instance Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
hostname text	Hostname (reference servers.server_name)
cluster_name text	Cluster name (reference current_setting('cluster_name'))
role text	Role, Primary if pg_is_in_recovery() = false, otherwise standby
release text	Version of LightDB, for example: LightDB 13.8-23.1
startup_time timestamp	Startup time

**F.34.2.1.5. sample\_kernel\_settings**

Sample kernel settings.

**Table F.20. sample\_kernel\_settings Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
name text	Name
value text	Value
sourcefile text	Source file

**F.34.2.1.6. sample\_cpu\_usage**

Sample cpu usage, the data is produced by analyzing statistics from /proc/stat.

**Table F.21. sample\_cpu\_usage Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
user_cpu float4	User cpu
sys_cpu float4	

Column Type	Description
	Sys cpu
idle_cpu float4	Idle cpu
io_wait float4	Io wait

#### F.34.2.1.7. sample\_db\_memory\_usage

Sample memory usage.

**Table F.22. sample\_db\_memory\_usage Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
shared_memory bigint	Shared memory size in bytes
local_memory bigint	Local memory size in bytes

#### F.34.2.1.8. sample\_settings

Sample settings.

**Table F.23. sample\_settings Columns**

Column Type	Description
server_id integer	Server id
first_seen timestamp (0) with time zone	First seen timestamp
setting_scope smallint	Scope of setting. Currently may be 1 for pg_settings and 2 for other adm functions (like version)
name text	Name
setting text	Setting
reset_val text	Reset val
boot_val text	Boot val
unit text	Unit
sourcefile text	Source file
sourceline integer	

Column Type	Description
	Source line
pending_restart boolean	Pending restart flag

### F.34.2.1.9. sample\_timings

Sample timings for various function call of sample system.

**Table F.24. sample\_timings Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
event text	Sample event
time_spent interval MINUTE TO SECOND (2)	Spent time for the related event on this sample

### F.34.2.1.10. baselines

Baselines setting.

**Table F.25. baselines Columns**

Column Type	Description
server_id integer	Server id
bl_id integer	Baseline sample id
bl_name varchar (25)	Baseline sample name
keep_until timestamp (0) with time zone	Timestamp indicating the end of life for this baseline sample

### F.34.2.1.11. bl\_samples

Baseline Sample list.

**Table F.26. bl\_samples Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
bl_id integer	Baseline id

**F.34.2.1.12. stmt\_list**

Statement list.

**Table F.27. stmt\_list Columns**

<b>Column Type</b>	<b>Description</b>
server_id integer	Server id
queryid_md5 char(32)	Md5 of the query id
query text	Query is a sql statement in text format

**F.34.2.1.13. sample\_stat\_database**

Sample statistic for database.

**Table F.28. sample\_stat\_database Columns**

<b>Column Type</b>	<b>Description</b>
server_id integer	Server id
sample_id integer	Sample id
datid oid	Database id
datname name	Database name
xact_commit bigint	Transaction commit count
xact_rollback bigint	Transaction rollback count
blks_read bigint	Blocks read count
blks_hit bigint	Blocks hit count
tup_returned bigint	Tuple returned count
tup_fetched bigint	Tuple fetched count
tup_inserted bigint	Tuple inserted count
tup_updated bigint	Tuple updated count
tup_deleted bigint	Tuple deleted count
conflicts bigint	Conflicts in total, including tablespace, lock, snapshot, bufferpin, startup_deadlock
temp_files bigint	

Column Type	Description
	Temporary files
temp_bytes bigint	Temporary files size in bytes
deadlocks bigint	Deadlocks
blk_read_time double precision	Block read time
blk_write_time double precision	Block write time
stats_reset timestamp with time zone	Timestamp of reset for the statistics.
datsize bigint	Database size
datsize_delta bigint	Database delta size
datistemplate boolean	True for a template database

#### F.34.2.1.14. sample\_statements

Sample statistic for statements.

**Table F.29. sample\_statements Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
userid oid	OID of user who executed the statement
datid oid	OID of database in which the statement was executed
queryid bigint	Internal hash code, computed from the statement's parse tree
queryid_md5 char(32)	Md5 of query, query is the sql statement in text format
plans bigint	Number of times the statement was planned (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
total_plan_time double precision	Total time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
min_plan_time double precision	Minimum time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
max_plan_time double precision	

<b>Column Type</b>	<b>Description</b>
	Maximum time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>mean_plan_time</code> double precision	Mean time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>stddev_plan_time</code> double precision	Population standard deviation of time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>calls</code> bigint	Number of times the statement was executed
<code>total_exec_time</code> double precision	Total time spent executing the statement, in milliseconds
<code>min_exec_time</code> double precision	Minimum time spent executing the statement, in milliseconds
<code>max_exec_time</code> double precision	Maximum time spent executing the statement, in milliseconds
<code>mean_exec_time</code> double precision	Mean time spent executing the statement, in milliseconds
<code>stddev_exec_time</code> double precision	Population standard deviation of time spent executing the statement, in milliseconds
<code>rows</code> bigint	Total number of rows retrieved or affected by the statement
<code>shared_blks_hit</code> bigint	Total number of shared block cache hits by the statement
<code>shared_blks_read</code> bigint	Total number of shared blocks read by the statement
<code>shared_blks_dirtied</code> bigint	Total number of shared blocks dirtied by the statement
<code>shared_blks_written</code> bigint	Total number of shared blocks written by the statement
<code>local_blks_hit</code> bigint	Total number of local block cache hits by the statement
<code>local_blks_read</code> bigint	Total number of local blocks read by the statement
<code>local_blks_dirtied</code> bigint	Total number of local blocks dirtied by the statement
<code>local_blks_written</code> bigint	Total number of local blocks written by the statement
<code>temp_blks_read</code> bigint	Total number of temp blocks read by the statement
<code>temp_blks_written</code> bigint	Total number of temp blocks written by the statement
<code>blk_read_time</code> double precision	Total time the statement spent reading blocks, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero)
<code>blk_write_time</code> double precision	

<b>Column Type</b>	<b>Description</b>
	Total time the statement spent writing blocks, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero)
<code>wal_records</code> bigint	Total number of WAL records generated by the statement
<code>wal_fpi</code> bigint	Total number of WAL full page images generated by the statement
<code>wal_bytes</code> numeric	Total amount of WAL generated by the statement in bytes

### F.34.2.1.15. `sample_statements_total`

Sample statistic for statements in total, group by database.

**Table F.30. `sample_statements_total` Columns**

<b>Column Type</b>	<b>Description</b>
<code>server_id</code> integer	Server id
<code>datid</code> oid	OID of database in which the statement was executed
<code>plans</code> bigint	Number of times the statement was planned (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>total_plan_time</code> double precision	Total time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>calls</code> bigint	Number of times the statement was executed
<code>total_exec_time</code> double precision	Total time spent executing the statement, in milliseconds
<code>rows</code> bigint	Total number of rows retrieved or affected by the database
<code>shared_blks_hit</code> bigint	Total number of shared block cache hits by the database
<code>shared_blks_read</code> bigint	Total number of shared blocks read by the database
<code>shared_blks_dirtied</code> bigint	Total number of shared blocks dirtied by the database
<code>shared_blks_written</code> bigint	Total number of shared blocks written by the database
<code>local_blks_hit</code> bigint	Total number of local block cache hits by the database
<code>local_blks_read</code> bigint	Total number of local blocks read by the database
<code>local_blks_dirtied</code> bigint	Total number of local blocks dirtied by the database
<code>local_blks_written</code> bigint	Total number of local blocks written by the database

<b>Column Type</b>	<b>Description</b>
temp_blks_read bigint	Total number of temp blocks read by the database
temp_blks_written bigint	Total number of temp blocks written by the statement by the database
blk_read_time double precision	Total time the statement spent reading blocks, in milliseconds (if track_io_timing is enabled, otherwise zero) by the database
blk_write_time double precision	Total time the statement spent writing blocks, in milliseconds (if track_io_timing is enabled, otherwise zero) by the database
wal_records bigint	Total number of WAL records generated by the database
wal_fpi bigint	Total number of WAL full page images generated by the database
wal_bytes numeric	Total amount of WAL generated by all statements in bytes by the database
statements bigint	Total statements count by the database

#### F.34.2.1.16. sample\_wait\_event\_total

Sample statistic for wait events in total.

**Table F.31. sample\_wait\_event\_total Columns**

<b>Column Type</b>	<b>Description</b>
server_id integer	Server id
sample_id integer	Sample id
pid integer	Backend process id related to this wait event
queryid bigint	Queryid related to the wait event
wait_event_type text	Wait event type in text
wait_event text	Wait event in text
wait_time double precision	Total wait time of this kind of event since the last sample
state text	Backend state in text

#### F.34.2.1.17. tablespaces\_list

Tablespaces, captured in samples.

**Table F.32. tablespaces\_list Columns**

Column Type	Description
server_id integer	Server id
tablespaceid oid	OID of the tablespace
tablespacename name	Name of the tablespace
tablespacepath oid	Path of the tablespace

**F.34.2.1.18. sample\_stat\_tablespaces**

Sample statistic for tablespace. The data is from the call of function `pg_tablespace_size(oid)`.

**Table F.33. sample\_stat\_tablespaces Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
tablespaceid oid	OID of tablespace
size integer	Total disk space used in the tablespace, in bytes
size_delta integer	Delta disk space compared with the size that captured by last sample, in bytes

**F.34.2.1.19. tables\_list**

Table list related to the server and database.

**Table F.34. tables\_list Columns**

Column Type	Description
server_id integer	Server id
datid oid	OID of the database
relid oid	Relid of the table (reference <code>pg_class.oid</code> )
relkind char(1)	Relkind of the table
reltoastrelid oid	OID of the TOAST table associated with this table (reference <code>pg_class.reltoastrelid</code> )
schemaname name	Schemaname of the table
relname name	

Column Type	Description
	Name of the table (reference pg_class.relname)

### F.34.2.1.20. sample\_stat\_tables

Sample statistic for tables.

**Table F.35. sample\_stat\_tables Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
datid oid	OID of the database
relid oid	Relid of the table (reference pg_class.oid)
tablespaceid oid	OID of tablespace (reference sample_stat_tablespace.tablespaceid)
seq_scan bigint	Delta of sequence scan since last sample
seq_tup_read bigint	Delta of sequence tuple read since last sample
idx_scan bigint	Delta of index scan since last scan
idx_tup_fetch bigint	Delta of index tuple fetch since last sample
n_tup_ins bigint	Delta of inserted tuple count since last sample
n_tup_upd bigint	Delta of updated tuple count since last sample
n_tup_del bigint	Delta of deleted tuple count since last sample
n_tup_hot_upd bigint	Delta of hot updated tuple count since last sample
n_live_tup bigint	Number of live tuple
n_dead_tup bigint	Number of dead tuple
n_mod_since_analyze bigint	Number of modified since analyze
n_ins_since_vacuum bigint	Number of inserted since vacuum
sample_id timestamp with time zone	Timestamp of last vacuum
last_autovacuum timestamp with time zone	Timestamp of last autovacuum

<b>Column Type</b>	<b>Description</b>
last_analyze timestamp with time zone	Timestamp of last analyze
last_autoanalyze timestamp with time zone	Timestamp of last autoanalyze
vacuum_count bigint	Delta vacuum count since last sample
autovacuum_count bigint	Delta autovacuum count since last sample
analyze_count bigint	Delta analyze count since last sample
autoanalyze_count bigint	Delta auto analyze count since last sample
heap_blks_read bigint	Delta heap block read since last sample
heap_blks_hit bigint	Delta heap block hit since last sample
idx_blks_read bigint	Delta index blocks read since last sample
toast_blks_read integer	Delta toast blocks read since last sample
toast_blks_hit integer	Delta toast blocks hit since last sample
tidx_blks_read integer	Delta toast index blocks read since last sample
tidx_blks_hit integer	Delta toast index blocks hit since last sample
relsize integer	Toast table size
relsize_diff integer	Delta toast table size since last sample

### F.34.2.1.21. sample\_stat\_tables\_total

Sample statistic for tables, group by server,sample\_id,datid,relkind,tablespaceid.

**Table F.36. sample\_stat\_tables\_total Columns**

<b>Column Type</b>	<b>Description</b>
server_id integer	Server id
sample_id integer	Sample id
datid oid	OID of the database
sample_id oid	OID of tablespace
relkind char(1)	

<b>Column Type</b>	<b>Description</b>
	Relkind of the table
seq_scan bigint	Total seq_scan since last sample
seq_tup_read bigint	Total seq_tup_read since last sample
idx_scan bigint	Total index scan since last sample
idx_tup_fetch bigint	Total index tuple fetched since last sample
n_tup_ins bigint	Total number of tuple inserted since last sample
n_tup_upd bigint	Total number of tuple updated since last sample
n_tup_del bigint	Total number of tuple deleted
n_tup_hot_upd bigint	Total number of hot tuple updated since last sample
sample_id bigint	Sample id
vacuum_count bigint	Total vacuum count since last sample
autovacuum_count bigint	Total auto vacuum count since last sample
analyze_count bigint	Total analyze count since last sample
autoanalyze_count bigint	Total auto analyze count since last sample
heap_blks_read bigint	Total heap blocks read since last sample
heap_blks_hit bigint	Total heap blocks hit since last sample
idx_blks_read bigint	Total index blocks read since last sample
idx_blks_hit bigint	Total index blocks hit since last sample
toast_blks_read bigint	Total toast blocks read since last sample
toast_blks_hit bigint	Total toast blocks hit since last sample
tidx_blks_read bigint	Total toast index blocks read since last sample
tidx_blks_hit bigint	Total toast index blocks hit since last sample
relsize_diff bigint	Delta disk space for the table since last sample

**F.34.2.1.22. indexes\_list**

Sample index list, including index names and schemas, captured in samples.

**Table F.37. indexes\_list Columns**

Column	Type	Description
server_id	integer	Server id
datid	oid	OID of database
indexrelid	oid	The OID of the pg_class entry for this index
relid	oid	The OID of the pg_class entry for the table this index is for
schemaname	name	Schema of the table
indexrelname	name	Name of the table

**F.34.2.1.23. sample\_stat\_indexes**

Sample statistic for indexes.

**Table F.38. samples Columns**

Column	Type	Description
server_id	integer	Server id
datid	oid	OID of database
tablespaceid	oid	OID of tablespace
idx_scan	bigint	Delta Index scan since last sample
idx_tup_read	bigint	Delta index tuple read since last sample
idx_tup_fetch	bigint	Delta index tuple fetch since last sample
idx_blks_read	bigint	Delta index blocks read since last sample
idx_blks_hit	bigint	Delta Index blocks hit since last sample
relsize	bigint	Current disk space for the index
relsize_diff	bigint	Delta disk space of the index since last sample
indisunique	bigint	If true, this is a unique index

**F.34.2.1.24. sample\_stat\_indexes\_total**

Sample statistic index, group by server\_id,sample\_id,datid,tablespaceid.

**Table F.39. sample\_stat\_indexes\_total Columns**

<b>Column Type</b>	<b>Description</b>
server_id integer	Server id
sample_id integer	Sample id
datid oid	OID of the database
tablespaceid oid	OID of tablespace
idx_scan bigint	Total index scan since last sample
idx_tup_read bigint	Total index tuple read since last sample
idx_tup_fetch bigint	Total index tuple fetch since last sample
idx_blks_read bigint	Total index blocks read since last sample
idx_blks_hit bigint	Total index blocks hit since last sample
relsize_diff bigint	Total delta disk space for the index since last sample

**F.34.2.1.25. funcs\_list**

Sample function list.

**Table F.40. funcs\_list Columns**

<b>Column Type</b>	<b>Description</b>
server_id integer	Server id
datid integer	OID of database
funcid oid	OID of the function (reference pg_proc.oid)
schemaname name	Schemaname of the function (reference pg_namespace.schemaname)
funcname name	Function name (reference pg_proc.proname)
funcargs text	Function arguments

**F.34.2.1.26. sample\_stat\_user\_functions**

Sample statistic for user functions.

**Table F.41. sample\_stat\_user\_functions Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
datid oid	OID of the database
funcid oid	OID of the function (reference pg_proc.oid)
calls bigint	Delta number of calls since last sample
total_time double precision	Delta total time since last sample
self_time double precision	Delta self time since last sample
trg_fn boolean	True if the data type of the function is trigger type

**F.34.2.1.27. sample\_stat\_user\_func\_total**

Sample statistic for user functions, group by server\_id,sample\_id,datid,trg\_fn.

**Table F.42. samples Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
datid oid	OID of database
calls bigint	Total number of calls since last sample
total_time double precision	Total function time since last sample
trg_fn boolean	True if the data type of the function is trigger type

**F.34.2.1.28. sample\_stat\_cluster**

Sample statistic for cluster.

**Table F.43. sample\_stat\_cluster Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	

<b>Column Type</b>	<b>Description</b>
Sample id	Sample id
checkpoints_timed bigint	Delta checkpoints timed since last sample
checkpoints_req bigint	Delta requested checkpoints since last sample
checkpoint_write_time double precision	Delta accumulated checkpoint write time since last sample, in milliseconds
checkpoint_sync_time double precision	Delta accumulated checkpoint sync time since last sample, in milliseconds
buffers_checkpoint bigint	Delta buffer written checkpoints since last sample
buffers_clean bigint	Delta number of dirty buffer written since last sample
maxwritten_clean bigint	Delta number of max written since last sample (count 1 once number of written >= bgwriter_lru_maxpages)
buffers_backend bigint	Delta number of buffer written requested by backend since last sample
buffers_backend_fsync bigint	Delta number of fsync done by backend since last sample
buffers_alloc bigint	Delta number of buffer allocated since last sample
stats_reset timestamp with time zone	Last timestamp that reset pg stat
wal_size bigint	Delta wal size since last sample (wal_size calculated by pg_wal_lsn_diff)

#### F.34.2.1.29. sample\_stat\_archiver

Sample statistic for archive actions including success and failure count and timestamp.

**Table F.44. sample\_stat\_archiver Columns**

<b>Column Type</b>	<b>Description</b>
server_id integer	Server id
sample_id integer	Sample id
archived_count integer	Last archive succeed count
last_archived_wal integer	Last archive wal file
last_archived_time integer	Last archive timestamp
failed_count integer	Last archive failed count
last_failed_wal integer	Last archive failed wal file

Column Type	Description
last_failed_time integer	Last archive failed timestamp
stats_reset integer	Timestamp of last reset for archive stat

### F.34.2.1.30. sample\_stat\_tables\_failures

Sample statistic for tables failures in calculating disk space.

**Table F.45. sample\_stat\_tables\_failures Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
datid oid	OID of database
relid oid	OID of the table (reference pg_class.oid)
size_failed boolean	True indicates a failure in calculating the disk space for the table
toastsize_failed boolean	True indicates a failure in calculating the disk space for the toast table

### F.34.2.1.31. sample\_stat\_indexes\_failures

Sample statistic for indexes failures.

**Table F.46. sample\_stat\_indexes\_failures Columns**

Column Type	Description
server_id integer	Server id
sample_id integer	Sample id
datid oid	OID of the database
indexrelid oid	OID of index (reference pg_index.indexrelid)
size_failed boolean	True indicates a failure in calculating the disk space for the index

### F.34.2.1.32. lt\_stat\_backend\_type\_id\_text

This table is utilized to pair the id and display text of each backend type. The backend type could be autovacuum launcher, autovacuum worker, client backend, background worker, background writer etc. Once a new backend type was added in postgresql, We have to add it in this table also. Available since LightDB 23.2 with lt\_profile 0.3.7.

**Table F.47. lt\_stat\_backend\_type\_id\_text Columns**

Column Type	Description
backend_type integer	Id of the backend type
backend_type_text text	Display text for the backend type

**F.34.2.1.33. lt\_stat\_cost\_type\_id\_text**

This table is utilized to pair the id and display text of each cost type. The cost type could be DB Time, DB Wait, DB CPU. Available since LightDB 23.2 with lt\_profile 0.3.7.

**Table F.48. lt\_stat\_cost\_type\_id\_text Columns**

Column Type	Description
cost_type integer	Id of the cost type
cost_type_text text	Display text for the cost type

**F.34.2.1.34. lt\_stat\_wait\_evt\_id\_text**

This table is utilized to pair the id and display text of each wait event type. Available since LightDB 23.2 with lt\_profile 0.3.7 .

**Table F.49. lt\_stat\_wait\_evt\_id\_text Columns**

Column Type	Description
evt_id integer	Id of the wait event type
evt_id_text text	Display text for the wait event type

**F.34.2.1.35. lt\_stat\_wait\_evt\_sub\_id\_text**

This table is utilized to pair the id and display text of each wait event type. Available since LightDB 23.2 with lt\_profile 0.3.7.

**Table F.50. lt\_stat\_wait\_evt\_sub\_id\_text Columns**

Column Type	Description
evt_id integer	Id of the wait event (reference lt_stat_wait_evt_id_text.evt_id)
evt_sub_id integer	Id of wait event type
evt_sub_id_text text	Display text for the wait event

**F.34.2.1.36. lt\_stat\_cost\_1s**

Sample statistic of accumulated cost time for DB Time, DB Wait. New sample would be inserted into this table by interval of 1 second. Available since LightDB 23.2 with lt\_profile 0.3.7.

**Table F.51. lt\_stat\_cost\_1s Columns**

<b>Column Type</b>	<b>Description</b>
bg_type INT	Id of backend type of this sample
cost_type INT	Id of cost type of this sample
evt_id INT	Id of wait event type of this sample
evt_sub_id INT	Id of wait event of this sample
cost BIGINT	Total spent time captured on this sample for the event, in microsecond

**F.34.2.1.37. lt\_stat\_cost\_60s**

Sample statistic for DB Wait related cost time. Accumulated in 1 minute by default, the archive action would be triggered in function call "collect\_activity\_profile" which would be scheduled every single minute by a default setting. Available since LightDB 23.2 with lt\_profile 0.3.7.

**Table F.52. lt\_stat\_cost\_60s Columns**

<b>Column Type</b>	<b>Description</b>
bg_type INT	Id of backend type of this sample
cost_type INT	Id of cost type of this sample
evt_id INT	Id of wait event type of this sample
evt_sub_id INT	Id of wait event of this sample
cost BIGINT	Total accumulated cost time captured on this archive cycle for the event, in microsecond

**F.34.2.1.38. lt\_stat\_cost\_600s**

Sample statistic for DB Wait related cost . Accumulated in 10 minutes by default, the archive action would be triggered in function call "take\_sample" which would be scheduled every 10 minutes by a default setting . The rows in this table would be CASCADE deleted by deleting rows from samples table. Available since LightDB 23.2 with lt\_profile 0.3.7.

**Table F.53. lt\_stat\_cost\_600s Columns**

<b>Column Type</b>	<b>Description</b>
server_id integer	Server id
sample_id integer	Sample id
bg_type INT	Id of backend type of this sample

Column Type	Description
cost_type INT	Id of cost type of this sample
evt_id INT	Id of wait event type of this sample
evt_sub_id INT	Id of wait event of this sample
cost BIGINT	Total accumulated cost time captured on this sample for the event, in microsecond

### F.34.3. Prerequisites

Although *lt\_profile* is usually installed in the target cluster, it also can collect performance data from other clusters. Hence, we have prerequisites for *lt\_profile* database, and for *servers*.

#### F.34.3.1. *lt\_profile* database prerequisites

*lt\_profile* extension depends on extensions *plpgsql*, *dblink* and *ltfce*.

#### F.34.3.2. Servers prerequisites

Consider setting following Statistics Collector parameters:

```
track_activities = on
track_counts = on
track_io_timing = on
track_functions = all/pl
```

To obtain statement statistics in reports, then database, mentioned in server connection string must have *lt\_stat\_statements* extension configured. Set *lt\_stat\_statements* parameters to meet your needs (see LightDB documentation):

- *lt\_stat\_statements.max* - low setting for this parameter may cause some statements statistics to be wiped out before sample is taken. Report will warn you if your *lt\_stat\_statements.max* is seems to be undersized.
- *lt\_stat\_statements.track* = 'top' - all value will affect accuracy of %Total fields for statements-related sections of a report.

### F.34.4. Creating Extensions

The most easy way is to install everything in public schema of a database:

```
lightdb@postgres=# CREATE EXTENSION dblink;
lightdb@postgres=# CREATE EXTENSION lt_stat_statements;
lightdb@postgres=# CREATE EXTENSION lt_stat_activity;
lightdb@postgres=# CREATE EXTENSION system_stats;
lightdb@postgres=# CREATE SCHEMA IF NOT EXISTS lt_catalog;
lightdb@postgres=# CREATE EXTENSION ltfce SCHEMA lt_catalog;
lightdb@postgres=# CREATE EXTENSION lt_profile;
```

If you want to install *lt\_profile* in other schema, just create it, and install extension in that schema:

```
lightdb@postgres=# CREATE EXTENSION dblink;
```

```
lightdb@postgres=# CREATE EXTENSION lt_stat_statements;
lightdb@postgres=# CREATE EXTENSION lt_stat_activity;
lightdb@postgres=# CREATE EXTENSION system_stats;
lightdb@postgres=# CREATE SCHEMA IF NOT EXISTS lt_catalog;
lightdb@postgres=# CREATE EXTENSION ltfce SCHEMA lt_catalog;
lightdb@postgres=# CREATE SCHEMA profile;
lightdb@postgres=# CREATE EXTENSION lt_profile SCHEMA profile;
```

All objects will be created in schema, defined by `SCHEMA` clause. Installation in dedicated schema is the recommended way - the extension will create its own tables, views, sequences and functions. It is a good idea to keep them separate. If you don't want to specify schema qualifier when using module, consider changing `search_path` setting.

## F.34.5. Privileges

Using `lt_profile` with a superuser privileges does not have any issues, but if you want to avoid using superuser permissions, here is the guide:

### F.34.5.1. On `lt_profile` database

Create an unprivileged user:

```
create role profile_usr login password 'pwd';
```

Create a schema for `lt_profile` installation:

```
create schema profile authorization profile_usr;
```

Grant usage permission on schema, where `dblink` extension resides:

```
grant usage on schema public to profile_usr;
```

Create the extension using `profile_usr` account:

```
lightdb@postgres=> create extension lt_profile schema profile;
```

### F.34.5.2. On server database

Create a user for `lt_profile` to connect:

```
create role profile_mon login password 'pwd_mon';
```

Make sure this user have permissions to connect to any database in a cluster (by default, it is), and `lt_hba.conf` will permit such connection from `lt_profile` database host. Also, we need `pg_read_all_stats` privilege, and execute privilege on `pg_stat_statements_reset`:

```
grant pg_read_all_stats to profile_mon;
grant execute on function pg_stat_statements_reset TO profile_mon;
```

### F.34.5.3. Server setup at `lt_profile` database

Non-superusers can't establish connection without a password. Best way to provide password is using a password file.

N.B. `lt_profile` will connect to all databases on a server, thus password file must use a wildcard as a database name.

As an insecure way, you can provide a password in connection string:

```
select server_connstr('local', 'dbname=postgres port=5432
user=profile_mon password=pwd_mon');
```

## F.34.6. Using `lt_profile`

### F.34.6.1. Setting extension parameters

You can define extension parameters in `lightdb.conf`. Default values:

- `lt_profile.topn = 10` - Number of top objects (statements, relations, etc.), to be reported in each sorted report table. Also, this parameter affects size of a sample - the more objects you want to appear in your report, the more objects we need to keep in a sample.
- `lt_profile.max_sample_age = 7` - Retention time of samples in days. Samples, aged `lt_profile.max_sample_age` days and more will be automatically deleted on next `take_sample()` call.
- `lt_profile.track_sample_timings = on` - when this parameter is on, `lt_profile` will track detailed sample taking timings.

### F.34.6.2. Managing servers

Once installed, extension will create one enabled *local* server - this is for cluster, where extension is installed.

Servers management functions:

- **`create_server(server name, server_connstr text, server_enabled boolean = TRUE, max_sample_age integer = NULL, description text = NULL)`** - creates a new server description  
Function arguments:
  - `server` - server name (must be unique)
  - `server_connstr` - server connection string
  - `enabled` - server enable flag. When is set, server will be included in the common `take_sample()` call
  - `max_sample_age` - server sample retention parameter overrides global `lt_profile.max_sample_age` setting for this server
  - `description` - server description text. Will be included in reports
- **`drop_server(server name)`** Drops a server and all its samples.
- **`enable_server(server name)`** Includes server in common `take_sample()` call.
- **`disable_server(server name)`** Excludes server from common `take_sample()` call.
- **`rename_server(server name, new_name name)`** Renames a server.
- **`set_server_max_sample_age(server name, max_sample_age integer)`** Set new retention period (in days) for a server. `max_sample_age` is integer value. To reset a server `max_sample_age` setting set it to `NULL`.
- **`set_server_db_exclude(server name, exclude_db name[])`** Set exclude databases list for a server. Used in cases, when you unable to connect to some databases in cluster (for example in Amazon RDS instances).
- **`set_server_connstr(server name, new_connstr text)`** Set new connection string for a server.
- **`set_server_description(server name, description text)`** Set new server description.
- **`show_servers()`** Display existing servers.

Server creation example:

```
SELECT server_new('omega','host=name_or_ip dbname=postgres
port=5432');
```

### F.34.6.3. Rare relation sizes collection

LightDB relation size functions may take considerable amount of time to collect sizes of all relations in a database. Also those functions require *AccessExclusiveLock* on a relation. However daily relation sizes collection may be quite enough for you. *lt\_profile* can skip relation sizes collection while taking samples guided by server size collection policy. Policy is defined as a daily window when relation size collection is permitted, and a minimal gap between two samples with relation sizes collected. Thus when size collection policy is defined sample taking function will collect relation sizes only when sample is taken in a window and previous sample with sizes is older then gap. Function *set\_server\_size\_sampling* defines this policy:

- *set\_server\_size\_sampling(server name, window\_start time with time zone = NULL, window\_duration interval hour to second = NULL, sample\_interval interval day to minute = NULL)*
  - *server* - server name
  - *window\_start* - size collection window start time
  - *window\_duration* - size collection window duration
  - *sample\_interval* - minimum time gap between two samples with relation sizes collected Size collection policy is defined only when all three parameters are set.

Example:

```
SELECT set_server_size_sampling('local','23:00+03',interval '2
hour',interval '8 hour');
```

Function *show\_servers\_size\_sampling* show defined sizes collection policy for all servers:

```
lightdb@postgres=# SELECT * FROM show_servers_size_sampling();
server_name | window_start | window_end | window_duration |
sample_interval
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
local      | 23:00:00+03 | 01:00:00+03 | 02:00:00      |
08:00:00
```

When you build a report between samples either of which lacks relation sizes data then relation growth sections will be excluded from report. However, *with\_growth* parameter of report generation functions will expand report bounds to nearest samples with relation sizes data collected. Relation sizes is needed for calculating sequentially scanned volume for tables and explicit vacuum load for indexes. When rare relation sizes collection is used, corresponding report sections data is based on linear interpolation.

### F.34.6.4. Samples

Every sample contains statistic information about database workload since previous sample.

#### F.34.6.4.1. Sample functions

- **take\_sample()** Function *take\_sample()* will collect a sample for all *enabled* servers. Server samples will be taken serially one by one. Function returns a table:

```
server      name,
result      text,
elapsed     interval
```

Where:

- *server* is a server name
- *result* is a result of taken sample. It can be 'OK' if sample was taken successively, and will contain error text in case of exception
- *elapsed* is a time elapsed taking a sample for *server* Such return makes it easy to control samples creation using SQL query.
- **take\_sample\_subset([sets\_cnt integer], [current\_set integer])** Due to serial samples processing *take\_sample()* function can take considerable amount of time. Function *take\_sample\_subset()* will take samples for a subset of enabled servers. It is convenient for parallel samples collection. *sets\_cnt* is number of servers subsets. *current\_set* is a subset to process, taking values between 0 and *sets\_cnt - 1* inclusive. Function returns a table:

```
server      name ,
result     text ,
elapsed    interval
```

Where:

- *server* is a server name
- *result* is a result of taken sample. It can be 'OK' if sample was taken successively, and will contain error text in case of exception
- *elapsed* is a time elapsed taking a sample for *server*
- **take\_sample(server name [, skip\_sizes boolean])** Will collect a sample for specified server. Use it, for example, when you want to use different sampling frequencies, or if you want to take explicit sample on a server.
  - *server* - name of a server to take sample
  - *skip\_sizes* - override server relation size collection policy. Policy applies only when *skip\_size* argument is omitted or set to null. *false* value of *skip\_sizes* argument cause take sample with relation sizes, while *true* will cause skipping relation sizes collection during a sample.
- **show\_samples([server name,] [days integer])** Returns a table, containing existing samples of a *server* (*local* server assumed if *server* is omitted) for *days* last days (all existing samples if omitted):

```
sample      integer ,
sample_time timestamp (0) with time zone ,
dbstats_reset timestamp (0) with time zone ,
clustats_reset timestamp (0) with time zone ,
archstats_reset timestamp (0) with time zone
```

Where:

- *sample* is a sample identifier
- *sample\_time* is a time when this sample was taken
- *dbstats\_reset*, *clustats\_reset* and *archstats\_reset* is usual null, but will contain *pg\_stat\_database*, *pg\_stat\_bgwriter* and *pg\_stat\_archiver* statistics reset timestamp if it was happend since previous sample Sample-collecting functions are also supports the server repository - it will delete obsolete samples and baselines with respect to *retention policy*.

#### F.34.6.4.2. Taking samples

You must create at least 2 samples to be able to build your first report between 1st and 2nd samples. Samples for all enabled servers are taken by calling *take\_sample()* function. There is no need in

frequent samples creation - usual essential frequency is one or two samples per hour. You can use cron-like tool to schedule samples creation. Example with 30 min period:

```
* /30 * * * * ltsql -c 'SELECT take_sample()' > /dev/null 2>&1
```

However, such call has no error checking on *take\_sample()* function results. Consider using more smart usage of *take\_sample()* function, providing results to your monitoring system.

Function will return 'OK' for all servers with successfully taken samples, and show error text for failed servers:

```
select * from take_sample();
  server |                                     result
-----+-----
ok_node | OK
        |                                     | 00:00:00.48
fail_node | could not establish connection
        |                                     +| 00:00:00
        | SQL statement "SELECT
dblink_connect('server_connection',server_connstr)" +|
PERFORM      | PL/pgSQL function take_sample(integer) line 69 at
        |                                     +|
line 27 at assignment+|
        | PL/pgSQL function take_sample_subset(integer,integer)
        | SQL function "take_sample" statement 1
        |                                     +|
        | FATAL: database "nodb" does not exist
        |
(2 rows)
```

### F.34.6.4.3. Sample data retention

We can't store sample data forever, thus we have a retention policy. You can define retentions on three levels:

- Setting parameter *lt\_profile.max\_sample\_age* in *lightdb.conf* file. This is a common retention, it is effective if none of others is defined.
- Define server *max\_sample\_age* setting while creating a server, or using *set\_server\_max\_sample\_age()* function for existing server. This setting overrides global *lt\_profile.max\_sample\_age* setting for a specific server.
- Create a baseline (see below). Baseline will override retention period for included samples with highest priority.

### F.34.6.4.4. Listing samples

Use *show\_samples()* function to get list of existing samples in the repository. This function will show detected statistics reset times.

### F.34.6.4.5. Sample taking timings

*lt\_profile* will collect detailed sample taking timing statistics when parameter *lt\_profile.track\_sample\_timings* is on. Results can be obtained from *v\_sample\_timings* view. *v\_sample\_timings* fields description:

- *server\_name* - sampled server name

- *sample\_id* - sample identifier
- *sample\_time* - when the sample was taken
- *event* - sample taking stage
- *time\_spent* - amount of time spent in the event

Event descriptions:

- **total** - Taking the sample (all stages).
- **connect** - Making dblink connection to the server.
- **get server environment** - Getting server GUC parameters, available extensions, etc.
- **collect database stats** - Querying the `pg_stat_database` view for statistics on databases.
- **calculate database stats** - Calculating differential statistics on databases since the previous sample.
- **collect tablespace stats** - Querying the `pg_tablespace` view for statistics on tablespaces.
- **collect statement stats** - Collecting statistics on statements using the `lt_stat_statements` extension.
- **query pg\_stat\_bgwriter** - Collecting cluster statistics using the `pg_stat_bgwriter` view.
- **query pg\_stat\_archiver** - Collecting cluster statistics using the `pg_stat_archiver` view.
- **collect object stats** - Collecting statistics on database objects. Includes following events:
  - **db:dbname collect tables stats** - Collecting statistics on tables for the *dbname* database.
  - **db:dbname collect indexes stats** - Collecting statistics on indexes for the *dbname* database.
  - **db:dbname collect functions stats** - Collecting statistics on functions for the *dbname* database.
- **maintain repository** - Executing support routines.
- **calculate tablespace stats** - Calculating differential statistics on tablespaces.
- **calculate object stats** - Calculating differential statistics on database objects. Includes following events:
  - **calculate tables stats** - Calculating differential statistics on tables of all databases.
  - **calculate indexes stats** - Calculating differential statistics on indexes of all databases.
  - **calculate functions stats** - Calculating differential statistics on functions of all databases.
- **calculate cluster stats** - Calculating cluster differential statistics.
- **calculate archiver stats** - Calculating archiver differential statistics.
- **delete obsolete samples** - Deleting obsolete baselines and samples.

### F.34.6.5. Baselines

Baseline is a named sample sequence, having its own retention setting. Baseline can be used in report-building functions as a sample interval. Undefined baseline retention means infinite retention. You can use baselines to save information about database workload on certain time period. For example, you may want to save samples, gathered during load testing, or during regular load on your system for further reference. Baseline management functions:

- **create\_baseline([server name,] baseline\_name varchar(25), start\_id integer, end\_id integer [, days integer])** - create a baseline
  - *server* - server name. *local* server is assumed if omitted
  - *name* - baseline name. Each baseline must have unique name within a server.
  - *start\_id, end\_id* - first and last samples, included in baseline.
  - *days* - baseline retention time. Defined in integer days since *now()*. This parameter may be omitted (or set to *null*), meaning infinite retention.
- **create\_baseline([server name,] baseline\_name varchar(25), time\_range tstzrange [, days integer])** - create a baseline
  - *server* - server name. *local* server is assumed if omitted
  - *name* - baseline name. Each baseline must have unique name within a server.
  - *time\_range* - baseline time interval. Baseline will include all available samples, overlapping this interval.
  - *days* - baseline retention time. Defined in integer days since *now()*. This parameter may be omitted (or be set to *null*), meaning infinite retention.
- **drop\_baseline([server name,] name varchar(25))** - drop a baseline
  - *server* - server name. *local* server is assumed if omitted
  - *name* - baseline name to drop. Dropping a baseline does not mean immediate drop of all its samples, they are just excluded from baseline, thus is not more covered with baseline retention.
- **keep\_baseline([server name,] name varchar(25) [, days integer])** - change retention of baselines
  - *server* - server name. *local* server is assumed if omitted
  - *name* - baseline name. This parameter may be omitted (or be set to *null*) to change retention of all existing baselines.
  - *days* - retention time of a baseline in days since *now()*. Also, may be omitted (or set to *null*) to set infinite retention.
- **show\_baselines([server name])** - displays existing baselines. Call this function to get information about existing baselines (names, sample intervals, and retention times)
  - *server* - server name. *local* server is assumed if omitted

```
lightdb@postgres=# SELECT * FROM baseline_show('local');
```

## F.34.6.6. Data export and import

Collected samples can be exported from instance of *lt\_profile* extension and then loaded into another one. This feature is useful when you want to move servers from one instance to another, or when you need to send collected data to your support team.

### F.34.6.6.1. Data export

Data is exported as a regular table by function `export_data()`. You can use any method to export this table from your database. For example, you can use *copy* command of *ltsql* to obtain single *.csv* file:

```
lightdb@postgres=# \copy (select * from export_data()) to
'export.csv'
```

By default `export_data()` function will export all samples of all configured servers. However you can limit export to only one server, and further limit sample range too:

- `export_data([server name, [min_sample_id integer,] [max_sample_id integer]] [, obfuscate_queries boolean])` - export collected data
  - `server` is a server name. All servers is assumed if omitted
  - `min_sample_id` and `max_sample_id` - export bounding sample identifiers (inclusive). Null value of `min_sample_id` bound cause export of all samples till `max_sample_id`, and null value of `max_sample_id` cause export of all samples since `min_sample_id`.
  - `obfuscate_queries` - use this parameter only when you want to hide query texts - they will be exported as MD5 hash.

### F.34.6.6.2. Data import

Data can be imported from local table only, thus previously exported data is need to be loaded first. In our case with `copy` command:

```
lightdb@postgres=# CREATE TABLE import (section_id bigint, row_data
  json);
CREATE TABLE
lightdb@postgres=# \copy import from 'export.csv'
COPY 6437
```

Now we can perform data import, providing this table to `import_data()` function:

```
lightdb@postgres=# SELECT * FROM import_data('import');
```

Although server descriptions is also imported, your local `lt_profile` servers with matching names will prohibit import operations. Consider temporarily rename those servers. If you'll need to import new data for previously imported servers, they will be matched by system identifier, so fell free to rename imported sever as you wish. All servers are imported in `disabled` state. `import_data()` function takes only the imported table:

- `import_data(data regclass)`
  - `data` - table containing exported data This function returns number of rows actually loaded in extension tables. After successful import operation you can drop `import` table.

### F.34.6.7. Reports

Reports are generated in HTML markup by reporting functions, which containing statistical information about instance workload during report interval.

#### F.34.6.7.1. PWR report functions

- `get_pwr([server name,] start_id integer, end_id integer [, description text [, with_growth boolean]])` - generate PWR report by sample identifiers
- `get_pwr([server name,] time_range tstzrange [, description text [, with_growth boolean]])` - generate PWR report for the shortest sample interval, covering provided `time_range`.
- `get_pwr([server name], baseline varchar(25) [, description text [, with_growth boolean]])` - generate PWR report, using baseline as samples interval
- `get_pwr_latest([server name])` - generate PWR report for two latest samples Function arguments:
  - `server` - server name. `local` server is assumed if omitted

- *start\_id* - interval begin sample identifier
- *end\_id* - interval end sample identifier
- *time\_range* - time range (*tstzrange* type)
- *baseline* - a baseline name
- *with\_growth* - a flag, requesting interval expansion to nearest bounds with relation growth data available. Default value is *false*
- *description* - a text memo, it will be included in report as a report description

### F.34.6.7.2. PSH report functions

- **get\_psh([server name,] start\_id integer, end\_id integer [, description text [, with\_growth boolean]])** - generate PSH report by sample identifiers
- **get\_psh([server name,] time\_range tstzrange [, description text [, with\_growth boolean]])** - generate PSH report for the shortest sample interval, covering provided *time\_range*.
- **get\_psh([server name], baseline varchar(25) [, description text [, with\_growth boolean]])** - generate PSH report, using baseline as samples interval
- **get\_psh\_latest([server name])** - generate PSH report for two latest samples Function arguments:
  - *server* - server name. *local* server is assumed if omitted
  - *start\_id* - interval begin sample identifier
  - *end\_id* - interval end sample identifier
  - *time\_range* - time range (*tstzrange* type)
  - *baseline* - a baseline name
  - *with\_growth* - a flag, requesting interval expansion to nearest bounds with relation growth data available. Default value is *false*
  - *description* - a text memo, it will be included in report as a report description

Report generation example:

```
$ ltsql -Aqtc "SELECT get_pwr(480,482)" -o report_480_482.html
```

For any other server, use it's name:

```
$ ltsql -Aqtc "SELECT get_pwr('omega',12,14)" -o
report_omega_12_14.html
```

Report generation using time ranges:

```
ltsql -Aqtc "select get_psh(tstzrange('2020-05-13
11:51:35+03', '2020-05-13 11:52:18+03'))" -o report_range.html
```

Also, time ranges is useful for generating periodic reports. Let's build last 24-hour report:

```
ltsql -Aqtc "select get_psh(tstzrange(now() - interval '1
day',now()))" -o last24h_report.html
```

Now you can view report file using any web browser.

## F.34.7. Sections of PWR report

Report tables and their columns are described in this section.

### F.34.7.1. Server statistics

#### F.34.7.1.1. CPU usage statistics

Contains cpu usage statistics such as user cpu, system cpu, idle cpu and iowait at the begin and end of report.

- *%User* - user cpu percent
- *%System* - system cpu percent
- *%Idle* - idle cpu percent
- *%IO Wait* - io wait cpu percent

#### F.34.7.1.2. Database memory usage statistics

Contains memory usage statistics of LightDB at the begin and end of report.

- *Host memory (MB)* - total physical memory of the host
- *Shared memory use (MB)* - shared memory used in LightDB, which is used by all processes of a LightDB server
- *Local memory use (MB)* - local memory used in LightDB, which is allocated by each backend process for its own use
- *Host memory used for shared memory+local memory (%)* - shared memory and local memory as a percentage of total host memory

#### F.34.7.1.3. Database statistics

Contains per-database statistics during report interval, based on *pg\_stat\_database* view.

- *Database* - database name
- *Transactions* - database transaction statistics
  - *Commits* - number of committed transactions (*xact\_commit*)
  - *Rollbacks* - number of rolled back transactions (*xact\_rollback*)
  - *Deadlocks* - number of deadlocks detected (*deadlocks*)
- *Block statistics* - database blocks read and hit statistics
  - *Hit(%)* - buffer cache hit ratio
  - *Read* - number of disk blocks read in this database (*blks\_read*)
  - *Hit* - number of times disk blocks were found already in the buffer cache (*blks\_hit*)
- *Tuples* - tuples statistics section
  - *Returned* - number of returned tuples (*tup\_returned*)
  - *Fetches* - number of fetched tuples (*tup\_fetched*)

- *Inserted* - inserted tuples count (*tup\_inserted*)
- *Updated* - number of updated tuples (*tup\_updated*)
- *Deleted* - number of deleted tuples (*tup\_deleted*)
- *Temp files* - temporary files statistics
  - *Size* - total amount of data written to temporary files by queries in this database (*temp\_bytes*)
  - *Files* - number of temporary files created by queries in this database (*temp\_files*)
- *Size* - database size at the end of report interval (*pg\_database\_size()*)
- *Growth* - database growth during report interval (*pg\_database\_size()* difference)

#### **F.34.7.1.4. Statement statistics by database**

Contains per-database aggregated total statistics of *pg\_stat\_statements* data (if *lt\_stat\_statements* extension was available during report interval)

- *Database* - database name
- *Calls* - total count of all statements executions (sum of *calls*)
- *Time (s)* - time spent in seconds
  - *Plan* - time spent planning (sum of *total\_plan\_time*) - available since *lt\_stat\_statements* 1.8
  - *Exec* - time spent executing (sum of *total\_time* or *total\_exec\_time*)
  - *Read* - time spent reading blocks (sum of *blk\_read\_time*)
  - *Write* - time spent writing blocks (sum of *blk\_write\_time*)
  - *Trigger* - time spent executing trigger functions
- *Fetches blocks* - total blocks fetched from disk and buffer cache
  - *Shared* - total fetched shared blocks count (sum of *shared\_blks\_read* + *shared\_blks\_hit*)
  - *Local* - total fetched local blocks count (sum of *local\_blks\_read* + *local\_blks\_hit*)
- *Dirtied blocks* - total blocks dirtied in database
  - *Shared* - total number of shared blocks dirtied in the database (sum of *shared\_blks\_dirtied*)
  - *Local* - total number of local blocks dirtied in the database (sum of *local\_blks\_dirtied*)
- *Temp blocks* - blocks used for operations (like joins and sorts)
  - *Read* - blocks read (sum of *temp\_blks\_read*)
  - *Write* - blocks written (sum of *temp\_blks\_written*)
- *Local blocks* - blocks used for temporary tables
  - *Read* - blocks read (sum of *local\_blks\_read*)
  - *Write* - blocks written (sum of *local\_blks\_written*)
- *Statements* - total count of captured statements

- *WAL size* - total amount of WAL generated by statements (sum of *wal\_bytes*)

### F.34.7.1.5. Cluster statistics

This table contains data from *pg\_stat\_bgwriter* view

- *Scheduled checkpoints* - total number of checkpoints, completed on schedule due to *checkpoint\_timeout* parameter (*checkpoints\_timed* field)
- *Requested checkpoints* - total number of other checkpoints: due to values of *max\_wal\_size*, *archive\_timeout* and CHECKPOINT commands (*checkpoints\_req* field)
- *Checkpoint write time (s)* - total time spent writing checkpoints in seconds (*checkpoint\_write\_time* field)
- *Checkpoint sync time (s)* - total time spent syncing checkpoints in seconds (*checkpoint\_sync\_time* field)
- *Checkpoints buffers written* - total number of buffers, written by checkpointer (*buffers\_checkpoint* field)
- *Background buffers written* - total number of buffers, written by background writer process (*buffers\_clean* field)
- *Backend buffers written* - total number of buffers, written by backends (*buffers\_backend* field)
- *Backend fsync count* - total number of backend fsync calls (*buffers\_backend\_fsync* field)
- *Bgwriter interrupts (too many buffers)* - total count of background writer interrupts due to reaching value of the *bgwriter\_lru\_maxpages* parameter.
- *Number of buffers allocated* - total count of buffers allocated (*buffers\_alloc* field)
- *WAL generated* - total amount of WAL generated (based on *pg\_current\_wal\_lsn()*)
- *WAL segments archived* - archived WAL segments count (based on *archived\_count* of *pg\_stat\_archiver* view)
- *WAL segments archive failed* - WAL segment archive failures count (based on *failed\_count* of *pg\_stat\_archiver* view)

### F.34.7.1.6. Tablespace statistics

This table contains information about tablespaces sizes and growth:

- *Tablespace* - tablespace name
- *Path* - tablespace path
- *Size* - tablespace size as it was at time of last sample in report interval
- *Growth* - tablespace growth during report interval

## F.34.7.2. Wait event statistics

This report section contains tables of top wait events statistics during report interval sorted by wait time.

### F.34.7.2.1. Main wait event type categories

- *IO* - Various file read/write activities during the query of sql statements.
- *LW Lock* - LW lock for a variable or LW lock acquire.

### F.34.7.2.2. Main wait event categories

- *WALSync* - Fsync XLOG file.
- *WALWrite* - Write Pages to XLOG file.
- *LockManager* - Used for the predicate locking target and lock shared hash tables to reduce contention.
- *WALInsert* - LW lock, Acquire a WAL insertion lock, for inserting to WAL.
- *DataFileExtend* - Add a block to the specified relation.
- *DataFileRead* - Read the specified block from a relation.
- *DataFileTruncate* - Truncate relation to specified number of blocks.
- *BufFileRead* - Load some data into buffer.
- *ProcArray* - LW lock for memory access across multi-process, such as ProcGlobal, ShmemVariableCache, MyPgXact, procArray.
- *RelationMapRead* - load data from the shared or local map file.
- *SLRUSync* - Physical write of a page from a buffer slot.
- *SLRUWrite* - Physical flush of a page from a buffer slot after writing.
- *RegisterSyncRequest* - RegisterSyncRequest.
- *XidGen* - LW lock, Set and return the next transaction ID.
- *XactSLRU* - LW lock, for xlog, clog related memory data.

### F.34.7.2.3. Top wait event type by wait time

This table contains top *lt\_profile.topn* wait event types sorted by wait time.

- *Wait Event Type* - Type of wait event, each type may contain several wait events.
- *Wait Time(s)* - Total wait time for all wait events of this type.
- *%Total Wait Time* - Total wait time of this type as a percentage of total wait time for all types of events in a cluster.

### F.34.7.2.4. Top wait event by wait time

This table contains top *lt\_profile.topn* wait events sorted by wait time.

- *Wait Event* - The specific event that process waiting for.
- *Wait Event Type* - Type of this event.
- *Wait Time(s)* - Total wait time of all this event.
- *%Total Wait Time* - Total wait time of all this event as a percentage of total wait time for all types of events in a cluster.

### F.34.7.3. SQL Query statistics

This report section contains tables of top statements during report interval sorted by several important statistics. Data is captured from *pg\_stat\_statements* view if it was available at the time of samples.

### F.34.7.3.1. Top SQL by elapsed time

This table contains top *lt\_profile.topn* statements sorted by elapsed time *total\_plan\_time + total\_exec\_time* of *pg\_stat\_statements* view.

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *%Total* - total time of this statement as a percentage of total time of all statements in a cluster
- *Time (s)* - time spent in this statement (in seconds)
  - *Elapsed* - total time, spent in this statement (*total\_plan\_time + total\_exec\_time*)
  - *Plan* - time spent in planning this statement (*total\_plan\_time* field)
  - *Exec* - time spent executing this query (*total\_exec\_time* field)
- *I/O time (s)*:
  - *Read* - time spent reading blocks (*blk\_read\_time* field)
  - *Write* - time spent writing blocks (*blk\_write\_time* field)
- *Plans* - number of times the statement was planned (*plans* field)
- *Executions* - number of times the statement was executed (*calls* field)

### F.34.7.3.2. Top SQL by planning time

Top *lt\_profile.topn* statements sorted by *total\_plan\_time* field of *pg\_stat\_statements* view

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *Plan elapsed (s)* - time spent in planning this statement (*total\_plan\_time* field)
- *%Elapsed* - plan time of this statement as a percentage of statement elapsed time
- *Plan times (ms)* - detailed plan time statistics of this statement (in milliseconds)
  - *Mean* - mean time spent planning this statement (*mean\_plan\_time* field)
  - *Min* - minimum time spent planning this statement (*min\_plan\_time* field)
  - *Max* - maximum time spent planning this statement (*max\_plan\_time* field)
  - *StdErr* - population standard deviation of time spent planning this statement (*stddev\_plan\_time* field)
- *Plans* - number of times this statement was planned (*plans* field)
- *Executions* - number of times this statement was executed (*calls* field)

### F.34.7.3.3. Top SQL by execution time

Top *lt\_profile.topn* statements sorted by *total\_time* (or *total\_exec\_time*) field of *pg\_stat\_statements* view

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *Exec (s)* - time spent executing this statement (*total\_exec\_time* field)
- *%Elapsed* - execution time of this statement as a percentage of statement elapsed time
- *%Total* - exec time of this statement as a percentage of total elapsed time of all statements in a cluster
- *I/O time (s)*:
  - *Read* - time spent reading blocks (*blk\_read\_time* field)
  - *Write* - time spent writing blocks (*blk\_write\_time* field)
- *Rows* - number of rows retrieved or affected by the statement (*rows* field)
- *Execution times (ms)* - detailed execution time statistics of this statement (in milliseconds)
  - *Mean* - mean time spent executing this statement (*mean\_exec\_time* field)
  - *Min* - minimum time spent executing this statement (*min\_exec\_time* field)
  - *Max* - maximum time spent executing this statement (*max\_exec\_time* field)
  - *StdErr* - population standard deviation of time spent executing this statement (*stddev\_exec\_time* field)
- *Executions* - number of times this statement was executed (*calls* field)

### F.34.7.3.4. Top SQL by executions

Top *lt\_profile.topn* statements sorted by *calls* field of *pg\_stat\_statements* view

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *Executions* - count of statement executions (*calls* field)
- *%Total* - *calls* of this statement as a percentage of total *calls* of all statements in a cluster
- *Rows* - number of rows retrieved or affected by the statement (*rows* field)
- *Mean(ms)* - mean time spent in the statement, in milliseconds (*mean\_time* or *mean\_exec\_time* field)
- *Min(ms)* - minimum time spent in the statement, in milliseconds (*min\_time* or *min\_exec\_time* field)
- *Max(ms)* - maximum time spent in the statement, in milliseconds (*max\_time* or *max\_exec\_time* field)
- *StdErr(ms)* - population standard deviation of time spent in the statement, in milliseconds (*stddev\_time* or *stddev\_exec\_time* field)

- *Elapsed(s)* - amount of time spent executing this query, in seconds (*total\_time* or *total\_exec\_time* field)

### F.34.7.3.5. Top SQL by I/O wait time

Top *lt\_profile.topn* statements sorted by read and write time (*blk\_read\_time* + *blk\_write\_time*)

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *IO(s)* - amount of time spent on reading and writing (I/O time) by this statement in seconds (*blk\_read\_time* + *blk\_write\_time*)
- *Read(s)* - amount of time spent on reading by this statement in seconds (*blk\_read\_time*)
- *Write(s)* - amount of time spent on writing by this statement in seconds (*blk\_write\_time*)
- *%Total* - I/O time of this statement as a percentage of total I/O time for all statements in a cluster
- *Reads* - number of blocks read by this statement divided in three sub-columns:
  - *Shared* - shared reads (*shared\_blks\_read* field)
  - *Local* - local reads (*local\_blks\_read* field)
  - *Temp* - temp reads (*temp\_blks\_read* field)
- *Writes* - number of blocks written by this statement divided in three sub-columns:
  - *Shared* - shared writes (*shared\_blks\_written* field)
  - *Local* - local writes (*local\_blks\_written* field)
  - *Temp* - temp writes (*temp\_blks\_written* field)
- *Elapsed(s)* - amount of time spent executing this query, in seconds (*total\_time* or *total\_exec\_time* field)
- *Executions* - number of executions for this statement (*calls* field)

### F.34.7.3.6. Top SQL by shared blocks fetched

Top *lt\_profile.topn* statements sorted by read and hit blocks, helping to detect the most data processing statements.

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *Fetched* - number of fetched blocks (expression: *shared\_blks\_hit* + *shared\_blks\_read*)
- *%Total* - blocks fetched for this statement as a percentage of total blocks fetched for all statements in a cluster
- *Hits(%)* - percentage of blocks got from buffers within all blocks got

- *Elapsed(s)* - amount of time spent in this statement, in seconds (*total\_time* or *total\_exec\_time* + *total\_plan\_time* field)
- *Rows* - number of rows retrieved or affected by the statement (*rows* field)
- *Executions* - number of executions for this statement (*calls* field)

#### F.34.7.3.7. Top SQL by shared blocks read

Top *lt\_profile.topn* statements sorted by shared reads, helping to detect most read intensive statements.

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *Reads* - number of shared read blocks for this statement (*shared\_blks\_read* field)
- *%Total* - shared reads for this statement as a percentage of total shared reads for all statements in a cluster
- *Hits(%)* - percentage of blocks got from buffers within all blocks got
- *Elapsed(s)* - amount of time spent in this statement, in seconds (*total\_time* or *total\_exec\_time* + *total\_plan\_time* field)
- *Rows* - number of rows retrieved or affected by the statement (*rows* field)
- *Executions* - number of executions for this statement (*calls* field)

#### F.34.7.3.8. Top SQL by shared blocks dirtied

Top *lt\_profile.topn* statements sorted by shared dirtied buffer count, helping to detect most data changing statements.

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *Dirtied* - number of shared blocks dirtied by this statement (*shared\_blks\_dirtied* field)
- *%Total* - shared blocks dirtied by this statement as a percentage of total shared blocks dirtied by all statements in a cluster
- *Hits(%)* - percentage of blocks got from buffers within all blocks got
- *Elapsed(s)* - amount of time spent in this statement, in seconds (*total\_time* or *total\_exec\_time* + *total\_plan\_time* field)
- *Rows* - number of rows retrieved or affected by the statement (*rows* field)
- *Executions* - number of executions for this statement (*calls* field)

#### F.34.7.3.9. Top SQL by shared blocks written

Top *lt\_profile.topn* statements, which had to perform writes sorted by written blocks count.

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *Written* - number of blocks written by this statement (*shared\_blks\_written* field)
- *%Total* - number of blocks written by this statement as a percentage of total blocks written by all statements in a cluster
- *%BackendW* - number of blocks written by this statement as a percentage of all blocks written in a cluster by backends (*buffers\_backend* field of *pg\_stat\_bgwriter* view)
- *Hits(%)* - percentage of blocks got from buffers within all blocks got
- *Elapsed(s)* - amount of time spent in this statement, in seconds (*total\_time* or *total\_exec\_time* + *total\_plan\_time* field)
- *Rows* - number of rows retrieved or affected by the statement (*rows* field)
- *Executions* - number of executions for this statement (*calls* field)

#### F.34.7.3.10. Top SQL by WAL size

Top *lt\_profile.topn* statements, sorted by WAL generated (available since *lt\_stat\_statements* v1.8)

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *WAL* - amount of WAL generated by the statement (*wal\_bytes* field)
- *%Total* - amount of WAL generated by the statement as a percentage of total WAL generated in cluster (*pg\_current\_wal\_lsn()* increment)
- *Dirtied* - number of shared blocks dirtied by this statement (*shared\_blks\_dirtied* field)
- *WAL full page images* - total number of WAL full page images generated by the statement (*wal\_fpi* field)
- *WAL records* - total amount of WAL bytes generated by the statement (*wal\_bytes* field)

#### F.34.7.3.11. Top SQL by temp usage

Top *lt\_profile.topn* statements sorted by temp I/O, calculated as the sum of *temp\_blks\_read*, *temp\_blks\_written*, *local\_blks\_read* and *local\_blks\_written* fields

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Database* - Statement database name (derived from *dbid* field)
- *Local fetched* - number of retrieved local blocks (expression: *local\_blks\_hit* + *local\_blks\_read*)
- *Hits(%)* - percentage of local blocks got from temp buffers within all local blocks got

- *Local blocks* - I/O statistics of blocks used in temporary tables
  - *Write* - number of written local blocks (*local\_blks\_written*)
  - *%Total* - *local\_blks\_written* of this statement as a percentage of total *local\_blks\_written* for all statements in a cluster
  - *Read* - number of read local blocks (*local\_blks\_read*)
  - *%Total* - *local\_blks\_read* of this statement as a percentage of total *local\_blks\_read* for all statements in a cluster
- *Temp blocks* - I/O statistics of blocks used in operations (like sorts and joins)
  - *Write* - number of written temp blocks (*temp\_blks\_written*)
  - *%Total* - *temp\_blks\_written* of this statement as a percentage of total *temp\_blks\_written* for all statements in a cluster
  - *Read* - number of read local blocks (*temp\_blks\_read*)
  - *%Total* - *temp\_blks\_read* of this statement as a percentage of total *temp\_blks\_read* for all statements in a cluster
- *Elapsed(s)* - amount of time spent in this statement, in seconds (*total\_time* or *total\_exec\_time* + *total\_plan\_time* field)
- *Rows* - number of rows retrieved or affected by the statement (*rows* field)
- *Executions* - number of executions for this statement (*calls* field)

### F.34.7.3.12. Complete list of SQL texts

Query texts of all statements mentioned in report. You can use *Query ID* link in any statistic table to get there and see query text.

## F.34.7.4. Schema object statistics

This section of report contains top database objects, using statistics from Statistics Collector views.

### F.34.7.4.1. Top tables by estimated sequentially scanned volume

Top database tables sorted by estimated volume, read by sequential scans. Based on *pg\_stat\_all\_tables* view. Here you can search for tables, possibly lacks some index on it.

- *Database* - database name of the table
- *Tablespace* - tablespace name, where the table is located
- *Schema* - schema name of the table
- *Table* - table name
- *~SeqBytes* - estimated volume, read by sequential scans. Calculated as a sum of *relation size* multiplied by *seq\_scan* for all samples of a report.
- *SeqScan* - number of sequential scans performed on the table (*seq\_scan* field)
- *IndexScan* - number of index scans initiated on this table (*idx\_scan* field)
- *IndexFetch* - number of live rows fetched by index scans (*idx\_tup\_fetch* field)
- *Inserted* - number of rows inserted (*n\_tup\_ins* field)

- *Updated* - number of rows updated (including HOT) (*n\_tup\_upd* field)
- *Deleted* - number of rows deleted (*n\_tup\_del* field)
- *HOT Updated* - number of rows HOT updated (*n\_tup\_hot\_upd* field)

#### F.34.7.4.2. Top tables by blocks fetched

Fetches block is a block being processed from disk (read), or from shared buffers (hit). Tables in this list are sorted by sum of fetched blocks for table relation, its indexes, TOAST of a table (if exists), and TOAST index (if exists). This section can focus your attention on tables with excessive blocks processing. Based on data of *pg\_statio\_all\_tables* view.

- *Database* - database name of the table
- *Tablespace* - tablespace name, where the table is located
- *Schema* - schema name of the table
- *Table* - table name
- *Heap* - statistics for relation blocks fetched (*heap\_blks\_read + heap\_blks\_hit*)
- *Index* - statistics for all relation indexes blocks fetched (*idx\_blks\_read + idx\_blks\_hit*)
- *TOAST* - statistics for TOAST-table blocks fetched (*toast\_blks\_read + toast\_blks\_hit*)
- *TOAST-Index* - statistics for TOAST index blocks fetched (*tidx\_blks\_read + tidx\_blks\_hit*)

Each statistic field in this table is divided in two columns:

- *Blocks* - number of blocks fetched for relation heap, index, TOAST or TOAST index
- *%Total* - blocks fetched for relation heap, index, TOAST or TOAST index as a percentage of all blocks fetched in a whole cluster

#### F.34.7.4.3. Top tables by blocks read

Top tables sorted by block reads. Tables in this list are sorted by sum of block reads for table, its indexes, TOAST of a table (if exists), and TOAST index (if exists). This section can focus your attention on tables with excessive blocks reading. Based on data of *pg\_statio\_all\_tables* view.

- *Database* - database name of the table
- *Tablespace* - tablespace name, where the table is located
- *Schema* - schema name of the table
- *Table* - table name
- *Heap* - statistics for relation block reads (*heap\_blks\_read*)
- *Index* - statistics for all relation indexes blocks reads (*idx\_blks\_read*)
- *TOAST* - statistics for TOAST-table block reads (*toast\_blks\_read*)
- *TOAST-Index* - statistics for TOAST index block reads (*tidx\_blks\_read*)

Each read statistic in this table is divided in two columns:

- *Blocks* - number of block reads for relation heap, index, TOAST or TOAST index
- *%Total* - block reads for relation heap, index, TOAST or TOAST index as a percentage of all block reads in a whole cluster

#### F.34.7.4.4. Top DML tables

Top tables sorted by amount of DML-affected rows, i.e. sum of *n\_tup\_ins*, *n\_tup\_upd* and *n\_tup\_del* (including TOAST tables).

- *Database* - database name of the table
- *Tablespace* - tablespace name, where the table is located
- *Schema* - schema name of the table
- *Table* - table name
- *Inserted* - number of rows inserted (*n\_tup\_ins* field)
- *Updated* - number of rows updated (including HOT) (*n\_tup\_upd* field)
- *Deleted* - number of rows deleted (*n\_tup\_del* field)
- *HOT Updated* - number of rows HOT updated (*n\_tup\_hot\_upd* field)
- *SeqScan* - number of sequential scans performed on the table (*seq\_scan* field)
- *SeqFetch* - number of live rows fetched by sequential scans (*seq\_tup\_read* field)
- *IndexScan* - number of index scans initiated on this table (*idx\_scan* field)
- *IndexFetch* - number of live rows fetched by index scans (*idx\_tup\_fetch* field)

#### F.34.7.4.5. Top tables by updated/deleted tuples

Top tables sorted by amount of operations, causing autovacuum load, i.e. sum of *n\_tup\_upd* and *n\_tup\_del* (including TOAST tables). Consider fine-tune of vacuum-related parameters based on provided vacuum and analyze run statistics.

- *Database* - database name of the table
- *Tablespace* - tablespace name, where the table is located
- *Schema* - schema name of the table
- *Table* - table name
- *Updated* - number of rows updated (including HOT) (*n\_tup\_upd* field)
- *HOT Updated* - number of rows HOT updated (*n\_tup\_hot\_upd* field)
- *Deleted* - number of rows deleted (*n\_tup\_del* field)
- *Vacuum* - number of times this table has been manually vacuumed (not counting VACUUM FULL) (*vacuum\_count* field)
- *AutoVacuum* - number of times this table has been vacuumed by the autovacuum daemon (*autovacuum\_count* field)
- *Analyze* - number of times this table has been manually analyzed (*analyze\_count* field)
- *AutoAnalyze* - number of times this table has been analyzed by the autovacuum daemon (*autoanalyze\_count* field)

#### F.34.7.4.6. Top growing tables

Top tables sorted by growth

- *Database* - database name of the table
- *Tablespace* - tablespace name, where the table is located
- *Schema* - schema name of the table
- *Table* - table name
- *Size* - table size, as it was at the moment of last sample in report interval
- *Growth* - table growth
- *Inserted* - number of rows inserted (*n\_tup\_ins* field)
- *Updated* - number of rows updated (including HOT) (*n\_tup\_upd* field)
- *Deleted* - number of rows deleted (*n\_tup\_del* field)
- *HOT Updated* - number of rows HOT updated (*n\_tup\_hot\_upd* field)

#### **F.34.7.4.7. Top indexes by blocks fetched**

Fetches block is a block being processed from disk (read), or from shared buffers (hit). Based on data of *pg\_statio\_all\_indexes* view.

- *Database* - database name of the index
- *Tablespace* - tablespace name, where the index is located
- *Schema* - schema name of the index
- *Table* - table name
- *Index* - index name
- *Scans* - number of scans, performed on index (*idx\_scan* field)
- *Blocks* - blocks fetched from this index (*idx\_blks\_read* + *idx\_blks\_hit*)
- *%Total* - blocks fetched for this index as a percentage of all blocks fetched in a whole cluster

#### **F.34.7.4.8. Top indexes by blocks read**

Top indexes sorted by block reads. Based on data of *pg\_statio\_all\_indexes* view.

- *Database* - database name of the index
- *Tablespace* - tablespace name, where the index is located
- *Schema* - schema name of the index
- *Table* - table name
- *Index* - index name
- *Scans* - number of scans, performed on index (*idx\_scan* field)
- *Block Reads* - number of disk blocks read from this index (*idx\_blks\_read*)
- *%Total* - block reads from this index as a percentage of all block reads in a whole cluster
- *Hits(%)* - percentage of index blocks got from buffer cache within all index blocks fetched for this index

#### F.34.7.4.9. Top growing indexes

Top indexes sorted by growth

- *Database* - database name of the index
- *Tablespace* - tablespace name, where the index is located
- *Schema* - schema name of the index
- *Table* - table name
- *Index* - index name
- *Index* - index statistics
  - *Size* - index size, as it was at the moment of last sample in report interval
  - *Growth* - index growth during report interval
- *Table* - underlying table statistics
  - *Inserted* - number of rows inserted into underlying table (*n\_tup\_ins* field)
  - *Updated* - number of rows updated in underlying table (without HOT) (*n\_tup\_upd* - *n\_tup\_hot\_upd*)
  - *Deleted* - number of rows deleted from underlying table (*n\_tup\_del* field)

#### F.34.7.4.10. Unused indexes

Non-scanned indexes during report interval sorted by DML operations on underlying tables, causing index support. Constraint indexes are excluded.

- *Database* - database name of the index
- *Tablespace* - tablespace name, where the index is located
- *Schema* - schema name of the index
- *Table* - table name
- *Index* - index name
- *Index* - index statistics
  - *Size* - index size, as it was at the moment of last sample in report interval
  - *Growth* - index growth during report interval
- *Table* - underlying table statistics
  - *Inserted* - number of rows inserted into underlying table (*n\_tup\_ins* field)
  - *Updated* - number of rows updated in underlying table (without HOT) (*n\_tup\_upd* - *n\_tup\_hot\_upd*)
  - *Deleted* - number of rows deleted from underlying table (*n\_tup\_del* field)

#### F.34.7.5. User function statistics

This report section contains top functions in cluster, based on *pg\_stat\_user\_functions* view.

### F.34.7.5.1. Top functions by total time

Top functions sorted by time elapsed.

- *Database* - database name of the function
- *Schema* - schema name of the index
- *Function* - function name
- *Executions* - number of times this function has been called (*calls* field)
- *Time (s)* - function timing statistics in seconds
  - *Total* - total time spent in this function and all other functions called by it (*total\_time* field)
  - *Self* - total time spent in this function itself, not including other functions called by it (*self\_time* field)
  - *Mean* - mean time of single function execution
  - *Mean self* - mean self time of single function execution

### F.34.7.5.2. Top functions by executions

Top functions sorted by executions count.

- *Database* - database name of the function
- *Schema* - schema name of the index
- *Function* - function name
- *Executions* - number of times this function has been called (*calls* field)
- *Time (s)* - function timing statistics in seconds
  - *Total* - total time spent in this function and all other functions called by it (*total\_time* field)
  - *Self* - total time spent in this function itself, not including other functions called by it (*self\_time* field)
  - *Mean* - mean time of single function execution
  - *Mean self* - mean self time of single function execution

### F.34.7.5.3. Top trigger functions by total time

Top trigger functions sorted by time elapsed.

- *Database* - database name of the function
- *Schema* - schema name of the index
- *Function* - function name
- *Executions* - number of times this function has been called (*calls* field)
- *Time (s)* - function timing statistics in seconds
  - *Total* - total time spent in this function and all other functions called by it (*total\_time* field)
  - *Self* - total time spent in this function itself, not including other functions called by it (*self\_time* field)

- *Mean* - mean time of single function execution
- *Mean self* - mean self time of single function execution

## F.34.7.6. Vacuum-related statistics

### F.34.7.6.1. Top tables by vacuum operations

Top tables sorted by vacuums (manual and automatic) processed

- *Database* - database name of the table
- *Tablespace* - tablespace name, where the table is located
- *Schema* - schema name of the table
- *Table* - table name
- *Vacuum count* - number of times this table has been manually vacuumed (not counting VACUUM FULL) (*vacuum\_count* field)
- *Autovacuum count* - number of times this table has been vacuumed by the autovacuum daemon (*autovacuum\_count* field)
- *Inserted* - number of rows inserted (*n\_tup\_ins* field)
- *Updated* - number of rows updated (including HOT) (*n\_tup\_upd* field)
- *Deleted* - number of rows deleted (*n\_tup\_del* field)
- *HOT Updated* - number of rows HOT updated (*n\_tup\_hot\_upd* field)

### F.34.7.6.2. Top tables by analyze operations

Top tables sorted by analyze run (manual and automatic) count

- *Database* - database name of the table
- *Tablespace* - tablespace name, where the table is located
- *Schema* - schema name of the table
- *Table* - table name
- *Analyze count* - number of times this table has been manually analyzed (*analyze\_count* field)
- *Autoanalyze count* - number of times this table has been analyzed by the autovacuum daemon (*autoanalyze\_count* field)
- *Inserted* - number of rows inserted (*n\_tup\_ins* field)
- *Updated* - number of rows updated (including HOT) (*n\_tup\_upd* field)
- *Deleted* - number of rows deleted (*n\_tup\_del* field)
- *HOT Updated* - number of rows HOT updated (*n\_tup\_hot\_upd* field)

### F.34.7.6.3. Top indexes by estimated vacuum I/O load

This table provides estimation of implicit vacuum load caused by table indexes. Here is top indexes sorted by count of vacuums performed on underlying table multiplied by index size.

- *Database* - database name of the index
- *Tablespace* - tablespace name, where the index is located
- *Schema* - schema name of the index
- *Table* - table name
- *Index* - index name
- *~Vacuum bytes* - vacuum load estimation calculated as  $(vacuum\_count + autovacuum\_count) * index\_size$
- *Vacuum count* - number of times this table has been manually vacuumed (not counting VACUUM FULL) (*vacuum\_count* field)
- *Autovacuum count* - number of times this table has been vacuumed by the autovacuum daemon (*autovacuum\_count* field)
- *Index size* - average index size during report interval
- *Resize* - average relation size during report interval

#### **F.34.7.6.4. Top tables by dead tuples ratio**

This section contains modified tables with last vacuum run. Statistics is valid for last sample in report interval. Based on *pg\_stat\_all\_tables* view.

Top tables, sized 5 MB and more, sorted by dead tuples ratio.

- *Database* - database name of the table
- *Schema* - schema name of the table
- *Table* - table name
- *Live* - estimated number of live rows (*n\_live\_tup*)
- *Dead* - estimated number of dead rows (*n\_dead\_tup*)
- *%Dead* - dead rows of the table as a percentage of all rows in the table
- *Last AutoVacuum* - last time when this table was vacuumed by the autovacuum daemon (*last\_autovacuum*)
- *Size* - table size, as it was at the moment of last report sample.

#### **F.34.7.6.5. Top tables by modified tuples ratio**

This section contains modified tables with last vacuum run. Statistics is valid for last sample in report interval. Based on *pg\_stat\_all\_tables* view.

Top tables, sized 5 MB and more, sorted by modified tuples ratio.

- *Database* - database name of the table
- *Schema* - schema name of the table
- *Table* - table name
- *Live* - estimated number of live rows (*n\_live\_tup*)
- *Dead* - estimated number of dead rows (*n\_dead\_tup*)

- *Mod* - estimated number of rows modified since this table was last analyzed (*n\_mod\_since\_analyze*)
- *%Mod* - modified rows of the table as a percentage of all rows in the table
- *Last AutoAnalyze* - last time when this table was analyzed by the autovacuum daemon
- *Size* - table size, as it was at the moment of last report sample.

### F.34.7.7. Cluster settings during the report interval

This section of a report contains LightDB GUC parameters, and values of functions *version()*, *pg\_postmaster\_start\_time()*, *pg\_conf\_load\_time()* and field *system\_identifier* of *pg\_control\_system()* function during report interval.

- *Setting* - name of a parameter
- *reset\_val* - *reset\_val* field of *pg\_settings* view. Bold font is used to show settings, changed during report interval.
- *Unit* - setting unit
- *Source* - configuration file, where this setting was defined, line number after semicolon.
- *Notes* - This field will contain timestamp of a sample, when this value was observed first time during report interval.

### F.34.7.8. Kernel settings during the report interval

This section of a report contains several important linux kernel parameters.

- *Setting* - name of a parameter
- *Value* - value of a parameter.
- *Source* - configuration file, where this setting was defined.

### F.34.7.9. What you need to remember...

1. LightDB collects execution statistics **after** execution is complete. If single execution of a statement lasts for several samples, it will affect statistics of only last sample (when it was completed). And you can't get statistics on still running statements. Also, maintenance processes like vacuum and checkpointer will update statistics only on completion.
2. Resetting any LightDB statistics may affect accuracy of a next sample.
3. Exclusive locks on relations conflicts with calculating relation size. Sample won't collect relation sizes of relations with AccessExclusiveLock held by any session. However, a session can acquire AccessExclusiveLock on relation during sample processing. To workaround this problem, *lock\_timeout* is set to 3s, so if *take\_sample()* function will be unable to acquire a lock for 3 seconds, it will fail, and no sample will be generated.

## F.34.8. Sections of PSH report

Report tables and their columns are described in this section.

### F.34.8.1. Top Wait Events

#### F.34.8.1.1. Top User Events

This table contains top *lt\_profile.topn* user wait event sorted by wait time.

- *Wait Event* - The specific event that process waiting for.
- *Wait Event Type* - Type of this event.
- *Wait Time(s)* - Total wait time of all this event.
- *%Total Wait Time* - Total wait time of all this event as a percentage of total wait time for all types of events in a cluster.

### F.34.8.1.2. Top Background Events

This table contains top *lt\_profile.topn* background wait event sorted by wait time.

- *Wait Event* - The specific event that process waiting for.
- *Wait Event Type* - Type of this event.
- *Wait Time(s)* - Total wait time of all this event.
- *%Total Wait Time* - Total wait time of all this event as a percentage of total wait time for all types of events in a cluster.

## F.34.8.2. Top SQL

### F.34.8.2.1. Top SQL with Top Events

Top wait events sorted by wait time for the top statements sorted by *total\_exec\_time* field of *pg\_stat\_statements* view.

- *Query ID* - Query identifier as a hash of database, user and query text. Compatible with *ltcenter* utility. Native *pg\_stat\_statements* field *qieryid* in hexadecimal notation is shown in square brackets.
- *SQL Text* - First 100 characters of the complete query.
- *Exec (s)* - time spent executing this statement (*total\_exec\_time* field).
- *%Total* - exec time of this statement as a percentage of total elapsed time of all statements in a cluster
- *Wait Event* - The specific event that process waiting for.
- *Wait Time(s)* - Total wait time of the event in this query.

### F.34.8.2.2. Complete list of SQL texts

Query texts of all statements mentioned in report. You can use *Query ID* link in any statistic table to get there and see query text.

## F.35. It\_qualstats

The *It\_qualstats* is a LightDB extension keeping statistics on predicates found in `WHERE` statements and `JOIN` clauses.

This is useful if you want to be able to analyze what are the most-often executed quals (predicates) on your database.

It also allows you to identify correlated columns, by identifying which columns are most frequently queried together.

The extension works by looking for known patterns in queries. Currently, this includes:

- Binary `OpExpr` where at least one side is a column from a table. Whenever possible, the predicate will be swapped so that `CONST OP VAR` expressions are turned into `VAR COMMUTED_OP`

CONST. AND and OR expression members are counted as separate entries. Ex: WHERE column1 = 2, WHERE column1 = column2, WHERE 3 = column3

- `ScalarArrayOpExpr` where the left side is a VAR, and the right side is an array constant. Those will be counted one time per element in the array. Ex: WHERE column1 IN (2, 3) will be counted as 2 occurrences for the (column1, '=') operator pair
- `BooleanTest` where the expression is a simple boolean column reference Ex: WHERE column1 IS TRUE Please not that clauses like WHERE columns1, WHERE NOT column1 won't be processed by `lt_qualstats` (yet)

This extension also saves the first query text, as-is, for each distinct queryid executed, with a limit of `lt_qualstats.max` entries.

Please not that the gathered data are not saved when the LightDB server is restarted.

## F.35.1. Configuration

The following GUCs can be configured, in `lightdb.conf`:

- `lt_qualstats.enabled` (boolean, default true): whether or not `lt_qualstats` should be enabled
- `lt_qualstats.track_constants` (boolean, default true): whether or not `lt_qualstats` should keep track of each constant value individually. Disabling this GUC will considerably reduce the number of entries necessary to keep track of predicates.
- `lt_qualstats.max`: the maximum number of predicated and query text tracked (defaults to 1000)
- `lt_qualstats.resolve_oids` (boolean, default false): whether or not `lt_qualstats` should resolve oids at query time, or just store the oids. Enabling this parameter makes the data analysis much more easy, since a connection to the database where the query was executed won't be necessary, but it will eat much more space (624 bytes per entry instead of 176). Additionally, this will require some catalog lookups, which aren't free.
- `lt_qualstats.track_pg_catalog` (boolean, default false): whether or not `lt_qualstats` should compute predicates on object in `pg_catalog` schema.
- `lt_qualstats.sample_rate` (double, default -1): the fraction of queries that should be sampled. For example, 0.1 means that only one out of ten queries will be sampled. The default (-1) means automatic, and results in a value of  $1 / \text{max\_connections}$ , so that statistically, concurrency issues will be rare.

## F.35.2. Updating the extension

Note that as all extensions configured in `shared_preload_libraries`, most of the changes are only applied once LightDB is restarted with the new shared library. The extension object itself only provides SQL wrappers to access internal data structures.

Also note that `lt_qualstats` doesn't provide extension upgrade scripts, as there's no data saved in any of the objects created. Therefore, you need to first drop the extension then create it again to get the new version.

## F.35.3. Usage

- Create the extension in any database:

```
CREATE EXTENSION lt_qualstats;
```

### F.35.3.1. Functions

The extension defines the following functions:

- `pg_qualstats`: returns the counts for every qualifier, identified by the expression hash. This hash identifies each expression.
- `userid`: oid of the user who executed the query.
- `dbid`: oid of the database in which the query has been executed.
- `lrelid`, `lattnum`: oid of the relation and attribute number of the VAR on the left hand side, if any.
- `opno`: oid of the operator used in the expression
- `rrelid`, `rattnum`: oid of the relation and attribute number of the VAR on the right hand side, if any.
- `qualid`: normalized identifier of the parent "AND" expression, if any. This identifier is computed excluding the constants. This is useful for identifying predicates which are used together.
- `uniquequalid`: unique identifier of the parent "AND" expression, if any. This identifier is computed including the constants.
- `qualnodeid`: normalized identifier of this simple predicate. This identifier is computed excluding the constants.
- `uniquequalnodeid`: unique identifier of this simple predicate. This identifier is computed including the constants.
- `occurences`: number of time this predicate has been invoked, ie. number of related query execution.
- `execution_count`: number of time this predicate has been executed, ie. number of rows it processed.
- `nbfiltered`: number of tuples this predicate discarded.
- `constant_position`: location of the constant in the original query string, as reported by the parser.
- `queryid`: if `pg_stats_statements` is installed, the `queryid` identifying this query, otherwise NULL.
- `constvalue`: a string representation of the right-hand side constant, if any, truncated to 80 bytes. Require to be superuser or member of `pg_read_all_stats`, "" will be showed instead.
- `eval_type`: evaluation type. 'f' for a predicate evaluated after a scan or 'i' for an index predicate.

Example:

```
ro=# select * from pg_qualstats;
userid # dbid # lrelid # lattnum #
opno # rrelid # rattnum # qualid # uniquequalid # qualnodeid #
uniquequalnodeid # occurences # execution_count # nbfiltered #
constant_position # queryid # constvalue # eval_type
```

```

-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----
10 # 16384 # 16385 # 2 # 98
# # # # # 115075651 #
1858640877 # 1 # 100000 # 99999 #
29 # # 'line 1'::text # f
10 # 16384 # 16391 # 2 # 98
# 16385 # 2 # # # 497379130 #
497379130 # 1 # 0 # 0 #
# # # f

```

- `pg_qualstats_index_advisor(min_filter, min_selectivity, forbidden_am)`: Perform a global index suggestion. By default, only predicates filtering at least 1000 rows and 30% of the rows in average will be considered, but this can be passed as parameter. You can also provide an array of index access method if you want to avoid some.

Example:

```

SELECT v
FROM json_array_elements(
pg_qualstats_index_advisor(min_filter
=> 50)->'indexes') v
ORDER BY v::text COLLATE "C";
v
-----
"CREATE INDEX ON public.adv USING btree
(id1)"
"CREATE INDEX ON public.adv USING btree
(val, id1, id2, id3)"
"CREATE INDEX ON public.pgqs USING btree
(id)"
(3 rows)

SELECT v
FROM json_array_elements(
pg_qualstats_index_advisor(min_filter
=> 50)->'unoptimised') v
ORDER BY v::text COLLATE "C";
v
-----
"adv.val ~~* ?"
(1 row)

```

- `pg_qualstats_deparse_qual`: format a stored predicate in the form `tablename. columnname operatorname ?`. This is mostly for the global index advisor.
- `pg_qualstats_get_idx_col`: for the given predicate, retrieve the underlying column name and all the possible operator class. This is mostly for the global index advisor.
- `pg_qualstats_get_qualnode_rel`: for the given predicate, return the underlying table, fully qualified. This is mostly for the global index advisor
- `pg_qualstats_example_queries`: return all the stored query texts.

- `pg_qualstats_example_query`: return the stored query text for the given queryid if any, otherwise NULL.
- `pg_qualstats_names`: return all the stored query texts.
- `pg_qualstats_reset`: reset the internal counters and forget about every encountered qual.

### F.35.3.2. Views

In addition to that, the extension defines some views on top of the `pg_qualstats` function:

- `pg_qualstats`: filters calls to `pg_qualstats()` by the current database.
- `pg_qualstats_pretty`: performs the appropriate joins to display a readable aggregated form for every attribute from the `pg_qualstats` view

Example:

```

ro=# select * from pg_qualstats_pretty;
      left_schema | left_table |
left_column | operator | right_schema | right_table |
right_column | occurrences | execution_count | nbfiltered
-----+-----+-----+-----+
+-----+-----+-----+-----+
      public | ltbench_accounts | aid |
| pg_catalog.= | 5 | 5000000 | 4999995 |
      public | ltbench_tellers | tid |
| pg_catalog.= | 10 | 10000000 | 9999990 |
      public | ltbench_branches | bid |
| pg_catalog.= | 10 | 2000000 | 1999990 |
      public | t1 | id |
| pg_catalog.= | public | t2 | id_t1 |
      1 | 10000 | 9999

```

- `pg_qualstats_all`: sums the counts for each attribute / operator pair, regardless of its position as an operand (LEFT or RIGHT), grouping together attributes used in AND clauses.

Example:

```

ro=# select * from pg_qualstats_all;
      dbid | relid | userid | queryid |
| attnums | opno | qualid | occurrences | execution_count |
nbfiltered | qualnodeid
-----+-----+-----+-----+
+-----+-----+-----+-----+
      16384 | 16385 | 10 | {2} |
| 98 | 1 | 100000 | 99999 |
115075651
      16384 | 16391 | 10 | {2} |
| 98 | 2 | 0 | 0 |
497379130

```

- `pg_qualstats_by_query`: returns only predicates of the form VAR OPERATOR CONSTANT, aggregated by queryid.

## F.36. It\_show\_plans

`lt_show_plans` is a module which shows the query plans of all currently running SQL statements. You can select the output format of plans: TEXT or JSON.

When the server starts, `lt_show_plans` makes a hashtable on the shared-memory in order to temporarily store query plans. The hashtable size cannot be changed, so the plans are not stored if the hashtable is full.

### F.36.1. Configuration Parameters

`lt_show_plans.plan_format`

It controls the output format of query plans. It can be selected either `text` or `json`. Default is `text`.

`lt_show_plans.max_plan_length`

It sets the maximum length of query plans. Default is 8192 [byte]. Note that this parameter must be set to an integer.

`lt_show_plans.show_level`

It controls the level of query plans. You can select one of `all`, `top` and `none`. "all" shows all level of the query plan. For example, when you execute a function defined by PL/pgSQL, the caller SQL statement (level 0) and the internal SQL statements in the function (level 1) are shown. "top" shows the top level of the query plan. "none" does not store the query plans, so the `lt_show_plans` view does not show anything. Default is `none`.

### F.36.2. Usage

You must add the line shown below in your `lightdb.conf` (See `lt_show_plans.show_level` above).

```
shared_preload_libraries = 'lt_show_plans'
lt_show_plans.show_level = 'top'
```

After starting your server, you must issue `CREATE EXTENSION` statement shown below.

```
testdb=# CREATE EXTENSION lt_show_plans;
```

After issuing, you must call the enable function shown below.

```
testdb=# select pg_show_plans_enable();
```

By issuing the following query, it shows the query plan and related information of the currently running SQL statements.

```
testdb=# SELECT * FROM pg_show_plans;
 pid | level | userid | dbid |
 plan
-----+-----+-----+-----
```

```
-----
```

```

11473 |      0 |      10 | 16384 | Function Scan on pg_show_plans
(cost=0.00..10.00 rows=1000 width=56)
11504 |      0 |      10 | 16384 | Function Scan on print_item
(cost=0.25..10.25 rows=1000 width=524)
11504 |      1 |      10 | 16384 | Result (cost=0.00..0.01 rows=1
width=4)
(3 rows)

```

pg\_show\_plans View:

- pid: the pid of the process which the query is running.
- level: the level of the query which runs the query. Top level is 0.
- userid: the userid of the user which runs the query.
- dbid: the database id of the database which the query is running.
- plan: the query plan of the running query.

If you need the query plans of running SQL statements and also the corresponding query string, you issue the following query which is combined with pg\_show\_plans and pg\_stat\_activity.

```

testdb=# \x
Expanded display is on.
testdb=# SELECT p.pid, p.level, p.plan, a.query FROM pg_show_plans
 p
  LEFT JOIN pg_stat_activity a
    ON p.pid = a.pid AND p.level = 0 ORDER BY p.pid, p.level;
-[ RECORD
 1 ]-----
pid   | 11473
level | 0
plan  | Sort (cost=72.08..74.58 rows=1000 width=80)
      |      +
      |      Sort Key: pg_show_plans.pid, pg_show_plans.level
      |      +
      |      -> Hash Left Join (cost=2.25..22.25 rows=1000 width=80)
      |      +
      |      Hash Cond: (pg_show_plans.pid = s.pid)
      |      +
      |      Join Filter: (pg_show_plans.level = 0)
      |      +
      |      -> Function Scan on pg_show_plans
(cost=0.00..10.00 rows=1000 width=48)      +
      |      -> Hash (cost=1.00..1.00 rows=100 width=44)
      |      +
      |      -> Function Scan on pg_stat_get_activity s
(cost=0.00..1.00 rows=100 width=44)
query | SELECT p.pid, p.level, p.plan, a.query FROM pg_show_plans p
      |      +
      |      LEFT JOIN pg_stat_activity a
      |      +
      |      ON p.pid = a.pid AND p.level = 0 ORDER BY p.pid,
p.level;
-[ RECORD
 2 ]-----
pid   | 11517
level | 0

```

```

plan | Function Scan on print_item (cost=0.25..10.25 rows=1000
      width=524)
query | SELECT * FROM print_item(1,20);
-[ RECORD
  3 ]-----
pid    | 11517
level  | 1
plan   | Result (cost=0.00..0.01 rows=1 width=4)
query  |

```

### F.36.3. Functions

- `pg_show_plans_disable()` disables the feature. Only superuser can execute it.
- `pg_show_plans_enable()` enables the feature. Only superuser can execute it.

## F.37. It\_sm

### F.37.1. What is It\_sm?

The `It_sm` extension provides SM cryptographic functions for LightDB, including `sm2`, `sm3`, `sm4` algorithms. Data can be encrypted and decrypted using the above algorithm.

Notice the current `It_sm` extension is an experimental trial version.

### F.37.2. function usage

#### F.37.2.1. SM2

SM2 is asymmetric encryption, there is a pair of keys, the private key is used for encryption, and the public key is used for decryption.

SM2 has a total of four functions:

- `gm_sm2_genprikey(local_storage bool)` return text generate the SM2 private key for encrypting data. The input parameter `true` indicates that the key is stored in the database, and the return value is `true` at this time. The input parameter `false` indicates that the key is imported from the outside when the database is restarted, and the return value is the private key string of text type.

```

-- Generate SM2 private key using local storage
SELECT gm_sm2_genprikey(true);
gm_sm2_genprikey
-----
true

-- Generate SM2 private key using external import
SELECT gm_sm2_genprikey(false);
gm_sm2_genprikey
-----
-----BEGIN EC PRIVATE KEY-----
+
MHcCAQEEIMattGsrutK0T7YftJ/nRL3HzUTSoBuW

qOqB8EYZkbMy12APj3sOBHq0krHUSlQ0UbVocJls+

```

```
v1JkxGQSJ+EGXbmuhRErwiAu9gTd8+umlw==
+
-----END EC PRIVATE KEY-----
+
```

- `gm_sm2_genpubkey((local_storage bool)` return text generate the SM2 public key for decrypting data. The input parameter `true` indicates that the key is stored in the database, and the return value is `true` at this time. The input parameter `false` indicates that the key is imported from the outside when the database is restarted, and the return value is the private key string of text type. Note that the private key must be generated using the `gm_sm2_genprikey()` function before the public key can be generated using this function.

```
-- Generate SM2 public key using local storage
SELECT gm_sm2_genpubkey(true);
gm_sm2_genprikey
-----
true

-- Generate SM2 public key using external import
SELECT gm_sm2_genpubkey(false);
gm_sm2_genpubkey
-----
-----BEGIN PUBLIC KEY-----
+

+
-----END PUBLIC KEY-----
+
```

- `gm_sm2_encrypt(plaintext bytea)` return `bytea` encrypt `plaintext` into `ciphertext`, input parameter as `plaintext` and return value as `ciphertext`.

```
-- Encrypt plaintext to generate ciphertext
select gm_sm2_encrypt('####LightDB_001');

gm_sm2_encrypt
-----
\x043f115fde4ad84ca331e6d6edbeb806d09ffa6094f8d52a57a39c7c6c587bcd06eb72146f3
```

- `gm_sm2_decrypt(ciphertext bytea)` return `bytea` decrypt the `ciphertext` into `plaintext`, the input parameter is the `ciphertext` and the return value is the `plaintext`.

```
-- Decrypt ciphertext to generate plaintext
select
gm_sm2_decrypt('\x043f115fde4ad84ca331e6d6edbeb806d09ffa6094f8d52a57a39c7c6c587bcd06eb72146f3')
gm_sm2_decrypt
-----
```

```
\xe68192e7949fe794b5e5ad904c6967687444425f303031

-- Convert the decrypted binary plaintext to display
select
convert_from('\xe68192e7949fe794b5e5ad904c6967687444425f303031',
'SQL_ASCII');
      convert_from
-----
####LightDB_001
```

### F.37.2.2. SM3

SM3 is a cryptographic hash algorithm, mainly used for digital signature and verification, message authentication code generation and verification, random number generation, etc.

SM3 has a total of one function:

- `gm_sm3_encrypt(plaintext bytea)` return `bytea` encrypt plaintext message to digest message, the input parameter is the plaintext message and the return value is the digest message.

```
-- plaintext message to generate digest message
select gm_sm3_encrypt('LightDB_002');
      gm_sm3_encrypt
-----

\x9de35b686bec17533e9ded7abfb039320bb08abbcec74eb0f44cf52b09e255c1
```

### F.37.2.3. SM4

SM4 is symmetric encryption, using CTR-128bit mode, there is a key for encryption and decryption.

SM4 has a total of three functions:

- `gm_sm4_genkey((local_storage bool)` return `text` generate the SM4 key for encrypting and decrypting data. The input parameter `true` indicates that the key is stored in the database, and the return value is `true` at this time. The input parameter `false` indicates that the key is imported from the outside when the database is restarted, and the return value is the key string of `text` type.

```
-- Generate SM4 key using local storage
select gm_sm4_genkey(true);
      gm_sm4_genkey
-----
true

-- Generate SM4 key using external import
select gm_sm4_genkey(false);
      gm_sm4_genkey
-----
A98B1904E5A74CDA5B2135519B941703
```

- `gm_sm4_encrypt(plaintext bytea)` return `bytea` encrypt plaintext into ciphertext, input parameter as plaintext and return value as ciphertext.

```
-- Encrypt plaintext to generate ciphertext
select gm_sm4_encrypt('###LightDB_003');
           gm_sm4_encrypt
-----
\x33e7117d0ce6f38ec2b78bfab08b991628771bedeeecf8
```

- gm\_sm4\_decrypt(ciphertext bytea) return bytea decrypt the ciphertext into plaintext, the input parameter is the ciphertext and the return value is the plaintext.

```
-- Decrypt ciphertext to generate plaintext
select
gm_sm4_decrypt('\x33e7117d0ce6f38ec2b78bfab08b991628771bedeeecf8');
           gm_sm4_decrypt
-----
\xe68192e7949fe794b5e5ad904c6967687444425f303033

-- Convert the decrypted binary plaintext to display
select
convert_from('\xe68192e7949fe794b5e5ad904c6967687444425f303033',
'SQL_ASCII');
           convert_from
-----
###LightDB_003
```

## F.37.3. key management

lt\_sm support two key management methods:

- The key is stored locally, and the input parameter is true in the use key generation function. After the key is generated, the encryption and decryption functions can be used.
- The key is imported from outside, and the input parameter of the generate key function is false. If the database is restarted, support for external import of key files.

```
-- When using lt_ctl, specify the -Y parameter to pass in the
key file
lt_ctl -D ./data -Y ./keyfile start
```

Among them, the key file needs to contain the keywords of username, database, sm2 private key, sm2 public key, sm4 key, use : separate keyword and value:

```
-- key file format, the corresponding pre-keyword and ':'
must contain
username:lightdb
database:postgres
sm2 private key:-----BEGIN EC PRIVATE KEY-----
MHcCAQEEIC4cBmYiht3Kf4e/

## F.38. It\_sql\_inspect

The `lt_sql_inspect` module provides two features: SQL best practices and SQL interception

### F.38.1. SQL best practices

#### F.38.1.1. Overview

This feature will provides rules to standardize sql writing.

There are two parts to this: LightDB DDL Specification Check and LightDB DML Specification Check.

#### F.38.1.2. Configuration Parameters

`lightdb_best_practice_mode` (String)

`lightdb_best_practice_mode` is used to specify the rules to check sql.

Now it support following rules:  
`keyword_not_allowed`,`bad_datatype`,`must_have_pk`,`must_have_gmt`,`no_more_100cols`,`no_paging`.

This setting can be changed within individual sessions.

`lightdb_best_practice_level` (String)

`lightdb_best_practice_level` is used to specify the message level when check failed.

It is used for both SQL best practices and SQL interception.

This setting can be changed within individual sessions.

#### F.38.1.3. LightDB DDL Specification Check

When you use DDL statements, LightDB will first check whether your statements comply with the specification.

At present, there are five checks: keyword check (including table name, field name, library name and index name), field type check (float,double,text,real, uuid,bytea,boolean,bit,character), whether the table must contain primary key, whether the table contains fields of creation time and last modification time, and the number of columns for operation does not exceed 100.The DDL statement specification supports:

```

CREATE DATABASE...
CREATE TABLE...
CREATE INDEX...
ALTER TABLE...

```

The keyword list can be referenced "[www.hs.net/lightdb/docs/current/sql-keywords-appendix.html](http://www.hs.net/lightdb/docs/current/sql-keywords-appendix.html)"

When you use nonstandard statements, you will report warnings or errors directly. For example:

```
create database text;
WARNING: LightDB DDL check warn! keyword not allowed with [db
name]:text

create table text(id int);
WARNING: LightDB DDL check warn! keyword not allowed with [table
name]:text
WARNING: LightDB DDL check warn! keyword not allowed with [column
name]:id
WARNING: LightDB DDL check warn! no primary key!
WARNING: LightDB DDL check warn! no gmt_create or no gmt_modified!
```

Where 'text' is a nonstandard database name, So report a warning. When creating a table, the table name is not standard, the column name is not standard, does not contain the primary key, does not contain the creation time and the last modification time, and the fields are warned. Of course, there is the upper limit of 100 operation columns, which is not listed here.

By default, DDL syntax checking is not enabled, There are two ways to turn it on. Global modification by modifying the configuration file:

```
lightdb_best_practice_level = 'warn'
lightdb_best_practice_mode = 'all'
```

A value of 'warn' for `lightdb_best_practice_level` indicates that the error level is warning. A value of 'error' indicates an error. When a nonstandard statement is detected, an error is reported directly#

```
create database text;
ERROR: LightDB DDL check error! keyword not allowed with [db
name]:text
```

If `lightdb_best_practice_mode` is configured as 'all', it means to check 5 types at the same time. Of course, you can combine the checks you want to configure at will, for example:

```
lightdb_best_practice_mode = 'keyword_not_allowed,must_have_pk'
```

The above configuration means that only keywords and primary keys are checked.

Another configuration method is session level modification:

```
set lightdb_best_practice_level to 'warn';
set lightdb_best_practice_mode to 'all';
```

There are five kinds of fully open here, and there is another way:

```
set lightdb_best_practice_mode to
'keyword_not_allowed,bad_datatype,must_have_pk,must_have_gmt,no_more_100cols';
```

#### F.38.1.4. LightDB DML Specification Check

When you use DML statements, LightDB will first check whether your statements comply with the specification.

At present, there is one check, no paging check: Remind the user when the user SQL does not specify query criteria or paging. The usage of these checks is described in detail below.

- `no_paging` check. Check is required in the following scenarios:
  - When the query statement has no `where` condition, no `limit` or no `offset`.
  - When the update statement has no `where` condition.
  - When the delete statement has no `where` condition.

How to use it? `lightdb_best_practice_level` and `lightdb_best_practice_mode` in the configuration file need to be configured.

By default, DML syntax checking is not enabled. Global modification by modifying the configuration file:

```
lightdb_best_practice_level = 'error'  
lightdb_best_practice_mode = 'all'
```

A value of 'warn' for `lightdb_best_practice_level` indicates that the error level is warning. A value of 'error' indicates an error. When a nonstandard statement is detected, an error is reported directly#

```
select * from table1;  
ERROR: LightDB DML check error! select sql not where/limit/offset  
clause!
```

If `lightdb_best_practice_mode` is configured as 'all', it means to check all types at the same time. Of course, you can combine the checks you want to configure at will, for example:

```
lightdb_best_practice_mode = 'no_paging'
```

## F.38.2. SQL interception

### F.38.2.1. Overview

This feature will intercept risk sql that match the specified rule in `lt_sql_inspect.secure_mode`.

Only SQL that operates on the specified database will be blocked, using `lt_sql_inspect.secure_enable_db` to specify the database

You can define a time frame by `lt_sql_inspect.secure_enable_time`, and only in this time frame sql will be intercepted. The time frame can only be within a day.

`lightdb_best_practice_level` controls the log level when SQL is intercepted. default is 'warn'. A value of 'warn' for `lightdb_best_practice_level` indicates that the error level is warning. A value of 'error' indicates an error.

Refer to `lt_sql_inspect.secure_mode` for detail rules.

### F.38.2.2. Configuration Parameters

`lt_sql_inspect.secure_mode` (String)

`lt_sql_inspect.secure_mode` specifies some SQL execution rules, such as intercepting SQL that meets the criteria. You can specify multiple rules, separated by commas. The following rules are supported: `select_without_where`, `update_without_where`, `delete_without_where`, `no_paging`, `high_risk_ddl`.

This setting can be changed within individual sessions.

- `select_without_where`: Block a select query that queries only one table when it has no where condition, no limit and no offset.
- `update_without_where`: Block a update query that queries only one table when it has no where condition, no limit and no offset.
- `delete_without_where`: Block a delete query that queries only one table when it has no where condition, no limit and no offset.
- `no_paging`: Equivalent to using `select_without_where`, `update_without_where`, and `delete_without_where` together.
- `high_risk_ddl`: Block following ddl: drop table, truncate table, alter table add/drop column, alter table add/drop Constraint, alter table modify column(null/not null, default/no default, type).

`lt_sql_inspect.secure_enable_time` (String)

`lt_sql_inspect.secure_enable_time` specifies the time frame, and only in this time frame, sql will be intercepted.

Format is 'start\_time - end\_time'(example: '09:00 - 18:00' ).

This parameter can only be set in the `lightdb.conf` file or on the server command line, and can be reload.

`lt_sql_inspect.secure_db` (String)

`lt_sql_inspect.secure_enable_db` specifies the databases, and only on these databases, sql will be intercepted.

You can specify multiple databases, separated by commas.

This parameter can only be set in the `lightdb.conf` file or on the server command line, and can be reload.

## F.38.2.3. Rules

### F.38.2.3.1. `select_without_where`

DQL involving only one table without where, limit and offset will be blocked.

When querying table under `pg_catalog`, `lt_catalog` or `ltcluster` scheme, sql will not be blocked. Note that when the `lightdb_best_practice_level` is error, the query of table in other schemas(include tables created by extension) that meet the requirements will report errors.

```
lightdb@lt_test=# set
  lt_sql_inspect.secure_mode=select_without_where;
SET
lightdb@lt_test=# select * from t1;
ERROR:  lt_sql_inspect: SQL cannot execute, because a full table
        scan or modification may be performed on the table "t1"
lightdb@lt_test=# select * from (select * from t1);
ERROR:  lt_sql_inspect: SQL cannot execute, because a full table
        scan or modification may be performed on the table "t1"
lightdb@lt_test=# select * from t1 limit 1;
key1 | key2
-----+-----
(0 rows)
```

```
lightdb@lt_test=# select * from t1 offset 1;
key1 | key2
-----+-----
(0 rows)
```

DQL involving multi-table will not be blocked.

```
lightdb@lt_test=# select * from t1, t2;
key1 | key2 | key1
-----+-----+-----
(0 rows)
```

This also applies to the view just like a subquery.

```
lightdb@lt_test=# create view t1_v as select * from t1;
CREATE VIEW
lightdb@lt_test=# select * from t1_v;
ERROR:  lt_sql_inspect: SQL cannot execute, because a full table
        scan or modification may be performed on the table "t1"
lightdb@lt_test=# select * from t1_v where key1=1;
key1 | key2
-----+-----
(0 rows)
```

### F.38.2.3.2. update\_without\_where

Be similar to select\_without\_where, but for update statement.

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode =
'update_without_where';
SET
lightdb@lt_test=# update t1 set key1=1;
ERROR:  lt_sql_inspect: SQL cannot execute, because a full table
        scan or modification may be performed on the table "t1"
lightdb@lt_test=# update t1 set key1=1 limit 1;
UPDATE 0
lightdb@lt_test=# update t1 set key1=1 offset 1;
UPDATE 0
lightdb@lt_test=# update t1 set key1=1 from t2 ;
UPDATE 0
lightdb@lt_test=# update t1 set key1=1 from t2 where
        t1.key1=t2.key1;
UPDATE 0
```

### F.38.2.3.3. delete\_without\_where

Be similar to select\_without\_where, but for delete statement.

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode =
'delete_without_where';
SET
lightdb@lt_test=# delete from t1 ;
ERROR:  lt_sql_inspect: SQL cannot execute, because a full table
scan or modification may be performed on the table "t1"
lightdb@lt_test=# delete from t1 where key1=1;
DELETE 0
lightdb@lt_test=# delete from t1 limit 1;
DELETE 0
lightdb@lt_test=# delete from t1 offset 1;
DELETE 0
lightdb@lt_test=# delete from t1 using t2;
DELETE 0
lightdb@lt_test=# delete from t1 using t2 where t1.key1=t2.key1;
DELETE 0
```

#### F.38.2.3.4. no\_paging

Equivalent to using `select_without_where`, `update_without_where`, and `delete_without_where` together.

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode=no_paging;
SET
lightdb@lt_test=#
ERROR:  lt_sql_inspect: SQL cannot execute, because a full table
scan or modification may be performed on the table "t1"
lightdb@lt_test=# update t1 set key1=1;
ERROR:  lt_sql_inspect: SQL cannot execute, because a full table
scan or modification may be performed on the table "t1"
lightdb@lt_test=# delete from t1 ;
ERROR:  lt_sql_inspect: SQL cannot execute, because a full table
scan or modification may be performed on the table "t1"
```

#### F.38.2.3.5. high\_risk\_ddl

Currently the following ddl will be considered as a high risk ddl, and will be intercepted.

- drop table

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode = high_risk_ddl;
SET
lightdb@lt_test=# drop table t1;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
```

- truncate table

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode = high_risk_ddl;
SET
lightdb@lt_test=# truncate table t1;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
```

- alter table add column

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode = high_risk_ddl;
SET
lightdb@lt_test=# alter table t1 add column key3 int;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
```

- alter table drop column

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode = high_risk_ddl;
SET
lightdb@lt_test=# alter table t1 drop column key1;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
```

- alter table add constraint

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode = high_risk_ddl;
SET
lightdb@lt_test=# alter table t1 add constraint t_uq
unique(key1);
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
```

- alter table drop constraint

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode = high_risk_ddl;
SET
lightdb@lt_test=# alter table t1 drop constraint t_uq;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
```

- alter table modify/alter column(only the types in the following example will be blocked, including null/not-null, default/non-default, and type).

```
lightdb@lt_test=# set lt_sql_inspect.secure_mode = high_risk_ddl;
SET
lightdb@lt_test=# alter table t1 modify key2 bigint;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
lightdb@lt_test=#
lightdb@lt_test=# alter table t1 alter key2 type text;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
lightdb@lt_test=#
lightdb@lt_test=# alter table t1 modify key2 null;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
```

```
lightdb@lt_test=#
lightdb@lt_test=# alter table t1 alter key2 drop not null;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
lightdb@lt_test=#
lightdb@lt_test=# alter table t1 modify key2 not null;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
lightdb@lt_test=#
lightdb@lt_test=# alter table t1 alter key2 set not null;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
lightdb@lt_test=#
lightdb@lt_test=# alter table t1 modify key2 default 10;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
lightdb@lt_test=#
lightdb@lt_test=# alter table t1 alter key2 set default 10;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
lightdb@lt_test=#
lightdb@lt_test=# alter table t1 alter key2 drop default;
ERROR:  lt_sql_inspect: SQL cannot execute, because it is a high
risk ddl
lightdb@lt_test=#
```

## F.39. It\_standby\_forward

`lt_standby_forward` is a module which forwards SQL statements from a hot standby to primary, providing a facility to reduce loading of primary, and to allow clients query from standby. For example, clients can send INSERT, CREATE to a hot standby.

### F.39.1. Configuration Parameters

`lt_standby_forward.enable_forward`

It controls whether this feature is enabled or not user. Default is `off`. Set this option on standby, or for a single session.

### F.39.2. Usage

You must add the line shown below in your `lightdb.conf`.

```
shared_preload_libraries = 'lt_standby_forward'
```

### F.39.3. Authentication

`lt_standby_forward` uses `primary_conninfo` to connect to primary, appending current dbname and username (i.e. the db and user used to connect to standby) to `primary_conninfo`. The connection info looks like

```
primary_conninfo dbname=a_db user=a_user
application_name=lt_standby_forward options='-c opt1=value1 -c
opt2=value2'
```

It is not supported to set password. Config `lt_hba.conf` on primary, or put password in `passfile` on standby to avoid typing password.

## F.39.4. Features/Limitations

- Forwards DELETE, UPDATE, INSERT, SELECT with modifying CTE to primary.
- Forwards SELECT/CALL statements containing volatile function to primary, otherwise executes on standby.
- Executes read only transactions on standby, otherwise forwards to primary.
- DDL is not allowed in transactions.
- View is rewritten (expanded) on standby before forwarding to primary. Query fails if view contains objects cannot be accessed by current user.
- Executes SET on both sides, execute show on standby. Don't SET xxx\_timeout after connection established, set these parameters with ltsql/jdbc parameter options. For ltsql/jdbc options, only statement\_timeout, lock\_timeout and idle\_in\_transaction\_session\_timeout will be pass to primary.
- COPY FROM is not supported.
- CREATE TEMP/UNLOGGED TABLE is not supported.
- Utility commands not mentioned above are forwarded to primary.

## F.40. lt\_stat\_activity

This extension for LightDB add `lt_stat_activity` view.

### F.40.1. Concepts

This extension provides the `lt_stat_activity` view, which contains all `pg_stat_activity` fields and adds the `query_id` field, which is consistent with the `query_id` in `pg_stat_statements`. When waiting events occur, `lt_stat_activity` and `pg_stat_statements` can be used to analyze together by `query_id`.

### F.40.2. Prerequisites

`lt_stat_activity` extension depends on extension `lt_stat_statements`.

### F.40.3. Creating Extensions

you must add `lt_stat_activity` in `shared_preload_libraries`, and restart server is needed after modify `shared_preload_libraries`.

```
# lightdb.conf
shared_preload_libraries = 'lt_stat_statements,lt_stat_activity'
```

```
lightdb@postgres=# CREATE EXTENSION lt_stat_statements;
lightdb@postgres=# CREATE EXTENSION lt_stat_activity;
```

You can define extension parameters in `lightdb.conf`.

`lt_stat_activity.track = top` - default, track top level query.

`lt_stat_activity.track = none` - `query_id` field in `lt_stat_activity` is always null.

## F.41. lt\_stat\_statements

The `lt_stat_statements` module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `lt_stat_statements` to `shared_preload_libraries` in `lightdb.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module.

When `lt_stat_statements` is loaded, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides a view, `pg_stat_statements`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION lt_stat_statements`.

### F.41.1. The pg\_stat\_statements View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F.54.

**Table F.54. pg\_stat\_statements Columns**

Column	Type	Description
<code>userid</code>	<code>oid</code>	(references <code>pg_authid.oid</code> ) OID of user who executed the statement
<code>dbid</code>	<code>oid</code>	(references <code>pg_database.oid</code> ) OID of database in which the statement was executed
<code>queryid</code>	<code>bigint</code>	Internal hash code, computed from the statement's parse tree
<code>query</code>	<code>text</code>	Text of a representative statement
<code>plans</code>	<code>bigint</code>	Number of times the statement was planned (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>total_plan_time</code>	<code>double precision</code>	Total time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>min_plan_time</code>	<code>double precision</code>	Minimum time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>max_plan_time</code>	<code>double precision</code>	Maximum time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>mean_plan_time</code>	<code>double precision</code>	Mean time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>stddev_plan_time</code>	<code>double precision</code>	Population standard deviation of time spent planning the statement, in milliseconds (if <code>lt_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>calls</code>	<code>bigint</code>	Number of times the statement was executed

<b>Column Type</b>	<b>Description</b>
total_exec_time double precision	Total time spent executing the statement, in milliseconds
min_exec_time double precision	Minimum time spent executing the statement, in milliseconds
max_exec_time double precision	Maximum time spent executing the statement, in milliseconds
mean_exec_time double precision	Mean time spent executing the statement, in milliseconds
stddev_exec_time double precision	Population standard deviation of time spent executing the statement, in milliseconds
rows bigint	Total number of rows retrieved or affected by the statement
shared_blks_hit bigint	Total number of shared block cache hits by the statement
shared_blks_read bigint	Total number of shared blocks read by the statement
shared_blks_dirtied bigint	Total number of shared blocks dirtied by the statement
shared_blks_written bigint	Total number of shared blocks written by the statement
local_blks_hit bigint	Total number of local block cache hits by the statement
local_blks_read bigint	Total number of local blocks read by the statement
local_blks_dirtied bigint	Total number of local blocks dirtied by the statement
local_blks_written bigint	Total number of local blocks written by the statement
temp_blks_read bigint	Total number of temp blocks read by the statement
temp_blks_written bigint	Total number of temp blocks written by the statement
blk_read_time double precision	Total time the statement spent reading blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time double precision	Total time the statement spent writing blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
wal_records bigint	Total number of WAL records generated by the statement
wal_fpi bigint	Total number of WAL full page images generated by the statement
wal_bytes numeric	Total amount of WAL generated by the statement in bytes

For security reasons, only superusers and members of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`) are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `lt_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of LightDB.

As a rule of thumb, `queryid` values can be assumed to be stable and comparable only so long as the underlying server version and catalog metadata details stay exactly the same. Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `lt_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `lt_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

## F.41.2. Functions

`pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint)`  
returns void

`pg_stat_statements_reset` discards statistics gathered so far by `lt_stat_statements` corresponding to the specified `userid`, `dbid` and `queryid`. If any of the parameters are not specified, the default value 0(invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0(invalid), it will discard all statistics. By default, this function can only be executed by superusers. Access may be granted to others using GRANT.

`pg_stat_statements(showtext boolean)` returns setof record

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the OUT argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `lt_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

## F.41.3. Configuration Parameters

`lt_stat_statements.max` (integer)

`lt_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

`lt_stat_statements.track` (enum)

`lt_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`lt_stat_statements.track_utility` (boolean)

`lt_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`lt_stat_statements.track_planning` (boolean)

`lt_stat_statements.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`lt_stat_statements.save` (boolean)

`lt_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `lightdb.conf` file or on the server command line.

The module requires additional shared memory proportional to `lt_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `lt_stat_statements.track` is set to none.

These parameters must be set in `lightdb.conf`. Typical usage might be:

```
# lightdb.conf
shared_preload_libraries = 'lt_stat_statements'

lt_stat_statements.max = 10000
lt_stat_statements.track = all
```

## F.41.4. Sample Output

## F.41.5. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

## F.42. lt\_tempfile

lt\_tempfile provides a number of support functions to managing temporary files generated when work memory is not enough. For more detail, please refer to work\_mem and lightdb\_keep\_temp\_file.

**Table F.55. lt\_tempfile Functions**

Function	Description
lt_catalog.lt_remove_temp_file(mode text) → setof record	removing temporary file. 's' is used for the current session, '*' is used for all session. For example: select lt_remove_temp_file('*').
lt_catalog.lt_list_temp_file(mode text) → boolean	listing temporary file. 's' is used for the current session, '*' is used for all session. For example: select lt_remove_temp_file('*').

`lt_remove_temp_file` removes the temporary file in the `LTDATA/base/ltsql_tmp/keep` directory. Returns true on success, false if the specified file is not present or the `lt_remove_temp_file()` call fails; other cases throw errors.

`lt_list_temp_file` returns the start timestamps, path names and Number of temporary files of all the files in the `LTDATA/base/ltsql_tmp` directory.

## F.43. It\_trgm

The `lt_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

### F.43.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

#### Note

`lt_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at ”. The set of trigrams in the string “foo|bar” is “ f”, “ fo”, “foo”, “oo ”, “ b”, “ ba”, “bar”, and “ar ”.

### F.43.2. Functions and Operators

The functions provided by the `lt_trgm` module are shown in Table F.56, the operators in Table F.57.

**Table F.56. `lt_trgm` Functions**

Function	Description
<code>similarity(text, text) → real</code>	Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).
<code>show_trgm(text) → text[]</code>	Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)
<code>word_similarity(text, text) → real</code>	Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.
<code>strict_word_similarity(text, text) → real</code>	

Function	Description
	Same as <code>word_similarity</code> , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.
<code>show_limit () → real</code>	Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. ( <i>Deprecated</i> ; instead use <code>SHOW lt_trgm.similarity_threshold</code> .)
<code>set_limit (real) → real</code>	Sets the current similarity threshold that is used by the <code>%</code> operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. ( <i>Deprecated</i> ; instead use <code>SET lt_trgm.similarity_threshold</code> .)

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
word_similarity
-----
                0.8
(1 row)
```

In the first string, the set of trigrams is { " w", " wo", "wor", "ord", "rd " }. In the second string, the ordered set of trigrams is { " t", " tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds " }. The most similar extent of an ordered set of trigrams in the second string is { " w", " wo", "wor", "ord" }, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is { " w", " wo", "wor", "ord", "rds", "ds " }.

```
# SELECT strict_word_similarity('word', 'two words'),
       similarity('word', 'words');
strict_word_similarity | similarity
-----+-----
                0.571429 |    0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

**Table F.57. `lt_trgm` Operators**

Operator	Description
<code>text % text → boolean</code>	Returns true if its arguments have a similarity that is greater than the current similarity threshold set by <code>lt_trgm.similarity_threshold</code> .

<b>Operator</b>	<b>Description</b>
<code>text &lt;% text → boolean</code>	Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>lt_trgm.word_similarity_threshold</code> parameter.
<code>text %&gt; text → boolean</code>	Commutator of the <code>&lt;%</code> operator.
<code>text &lt;&lt;% text → boolean</code>	Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>lt_trgm.strict_word_similarity_threshold</code> parameter.
<code>text %&gt;&gt; text → boolean</code>	Commutator of the <code>&lt;&lt;%</code> operator.
<code>text &lt;-&gt; text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.
<code>text &lt;&lt;-&gt; text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.
<code>text &lt;-&gt;&gt; text → real</code>	Commutator of the <code>&lt;&lt;-&gt;</code> operator.
<code>text &lt;&lt;&lt;-&gt; text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>strict_word_similarity()</code> value.
<code>text &lt;-&gt;&gt;&gt; text → real</code>	Commutator of the <code>&lt;&lt;&lt;-&gt;</code> operator.

### F.43.3. GUC Parameters

`lt_trgm.similarity_threshold` (real)

Sets the current similarity threshold that is used by the `%` operator. The threshold must be between 0 and 1 (default is 0.3).

`lt_trgm.word_similarity_threshold` (real)

Sets the current word similarity threshold that is used by the `<%` and `%>` operators. The threshold must be between 0 and 1 (default is 0.6).

`lt_trgm.strict_word_similarity_threshold` (real)

Sets the current strict word similarity threshold that is used by the `<<%` and `%>>` operators. The threshold must be between 0 and 1 (default is 0.5).

### F.43.4. Index Support

The `lt_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the

above-described similarity operators, and additionally support trigram-based index searches for LIKE, ILIKE, ~ and ~\* queries. (These indexes do not support equality nor simple comparison operators, so you may need a regular B-tree index too.)

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

`gist_trgm_ops` GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t
  gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
  FROM test_trgm
 WHERE t % 'word'
 ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to `word`, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
  FROM test_trgm
 ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
  FROM test_trgm
 WHERE 'word' <% t
 ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
  FROM test_trgm
```

```
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in LightDB 9.1, these index types also support index searches for LIKE and ILIKE, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in LightDB 9.3, these index types also support index searches for regular-expression matches (~ and ~\* operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both LIKE and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

## F.43.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM
documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

### Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

## F.44. `lt_visibility`

The `lt_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `lt_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than

only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

## F.44.1. Functions

`pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the PD\_ALL\_VISIBLE bit of that block.

`pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the PD\_ALL\_VISIBLE bit of each block.

`pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint)` returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first VACUUM executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and members of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

## F.44.2. Author

Robert Haas <rhaas@postgresql.org>

## F.45. Itaudit

### F.45.1. Introduction

The LightDB Audit Extension (Itaudit) provides detailed session and/or object audit logging via the standard LightDB logging facility.

The goal of the Itaudit is to provide LightDB users with capability to produce audit logs often required to comply with government, financial, or ISO certifications.

An audit is an official inspection of an individual's or organization's accounts, typically by an independent body. The information gathered by Itaudit is properly called an audit trail or audit log. The term audit log is used in this documentation.

### F.45.2. Why Itaudit?

Basic statement logging can be provided by the standard logging facility with `log_statement = all`. This is acceptable for monitoring and other usages but does not provide the level of detail generally required for an audit. It is not enough to have a list of all the operations performed against the database. It must also be possible to find particular statements that are of interest to an auditor. The standard logging facility shows what the user requested, while Itaudit focuses on the details of what happened while the database was satisfying the request.

For example, an auditor may want to verify that a particular table was created inside a documented maintenance window. This might seem like a simple job for `grep`, but what if you are presented with something like this (intentionally obfuscated) example:

```
DO $$
BEGIN
    EXECUTE 'CREATE TABLE import' || 'ant_table (id INT)';
END $$;
```

Standard logging will give you this:

```
LOG: statement: DO $$
BEGIN
    EXECUTE 'CREATE TABLE import' || 'ant_table (id INT)';
END $$;
```

It appears that finding the table of interest may require some knowledge of the code in cases where tables are created dynamically. This is not ideal since it would be preferable to just search on the table name. This is where Itaudit comes in. For the same input, it will produce this output in the log:

```
AUDIT: SESSION,33,1,FUNCTION,DO,,,"DO $$
BEGIN
    EXECUTE 'CREATE TABLE import' || 'ant_table (id INT)';
END $$;"
AUDIT: SESSION,33,2,DDL,CREATE
TABLE,TABLE,public.important_table,CREATE TABLE important_table
(id INT)
```

Not only is the DO block logged, but substatement 2 contains the full text of the CREATE TABLE with the statement type, object type, and full-qualified name to make searches easy.

When logging SELECT and DML statements, Itaudit can be configured to log a separate entry for each relation referenced in a statement. No parsing is required to find all statements that touch a particular

table. In fact, the goal is that the statement text is provided primarily for deep forensics and should not be required for an audit.

### F.45.3. Usage Considerations

Depending on settings, it is possible for `ltaudit` to generate an enormous volume of logging. Be careful to determine exactly what needs to be audit logged in your environment to avoid logging too much.

For example, when working in an OLAP environment it would probably not be wise to audit log inserts into a large fact table. The size of the log file will likely be many times the actual data size of the inserts because the log file is expressed as text. Since logs are generally stored with the OS this may lead to disk space being exhausted very quickly. In cases where it is not possible to limit audit logging to certain tables, be sure to assess the performance impact while testing and allocate plenty of space on the log volume. This may also be true for OLTP environments. Even if the insert volume is not as high, the performance impact of audit logging may still noticeably affect latency.

To limit the number of relations audit logged for `SELECT` and `DML` statements, consider using object audit logging (see Object Auditing). Object audit logging allows selection of the relations to be logged allowing for reduction of the overall log volume. However, when new relations are added they must be explicitly added to object audit logging. A programmatic solution where specified tables are excluded from logging and all others are included may be a good option in this case.

### F.45.4. Settings

Settings may be modified only by a superuser. Allowing normal users to change their settings would defeat the point of an audit log.

Settings can be specified globally (in `lightdb.conf` or using `ALTER SYSTEM ... SET`), at the database level (using `ALTER DATABASE ... SET`), or at the role level (using `ALTER ROLE ... SET`). Note that settings are not inherited through normal role inheritance and `SET ROLE` will not alter a user's `ltaudit` settings. This is a limitation of the roles system and not inherent to `ltaudit`.

The `ltaudit` extension must be loaded in `shared_preload_libraries`. Otherwise, an error will be raised at load time and no audit logging will occur. In addition, `CREATE EXTENSION ltaudit` must be called before `ltaudit.log` is set. If the `ltaudit` extension is dropped and needs to be recreated then `ltaudit.log` must be unset first otherwise an error will be raised.

#### F.45.4.1. ltaudit.log

Specifies which classes of statements will be logged by session audit logging. Possible values are:

- **READ**: `SELECT` and `COPY` when the source is a relation or a query.
- **WRITE**: `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation.
- **FUNCTION**: Function calls and `DO` blocks.
- **ROLE**: Statements related to roles and privileges: `GRANT`, `REVOKE`, `CREATE/ALTER/DROP ROLE`.
- **DDL**: All `DDL` that is not included in the `ROLE` class.
- **MISC**: Miscellaneous commands, e.g. `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, `SET`.
- **MISC\_SET**: Miscellaneous `SET` commands, e.g. `SET ROLE`.
- **ALL**: Include all of the above.

Multiple classes can be provided using a comma-separated list and classes can be subtracted by prefacing the class with a `-` sign (see Session Audit Logging).

The default is none.

### F.45.4.2. `ltaudit.log_catalog`

Specifies that session logging should be enabled in the case where all relations in a statement are in `pg_catalog`. Disabling this setting will reduce noise in the log from tools like `ltsql` and `PgAdmin` that query the catalog heavily.

The default is on.

### F.45.4.3. `ltaudit.log_client`

Specifies whether log messages will be visible to a client process such as `ltsql`. This setting should generally be left disabled but may be useful for debugging or other purposes.

Note that `ltaudit.log_level` is only enabled when `ltaudit.log_client` is on.

The default is off.

### F.45.4.4. `ltaudit.log_level`

Specifies the log level that will be used for log entries (see message levels for valid levels) but note that `ERROR`, `FATAL`, and `PANIC` are not allowed). This setting is used for regression testing and may also be useful to end users for testing or other purposes.

Note that `ltaudit.log_level` is only enabled when `ltaudit.log_client` is on; otherwise the default will be used.

The default is `log`.

### F.45.4.5. `ltaudit.log_parameter`

Specifies that audit logging should include the parameters that were passed with the statement. When parameters are present they will be included in CSV format after the statement text.

The default is off.

### F.45.4.6. `ltaudit.log_relation`

Specifies whether session audit logging should create a separate log entry for each relation (`TABLE`, `VIEW`, etc.) referenced in a `SELECT` or DML statement. This is a useful shortcut for exhaustive logging without using object audit logging.

The default is off.

### F.45.4.7. `ltaudit.log_statement_once`

Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry. Disabling this setting will result in less verbose logging but may make it more difficult to determine the statement that generated a log entry, though the statement/substatement pair along with the process id should suffice to identify the statement text logged with a previous entry.

The default is off.

### F.45.4.8. `ltaudit.role`

Specifies the master role to use for object audit logging. Multiple audit roles can be defined by granting them to the master role. This allows multiple groups to be in charge of different aspects of audit logging.

There is no default.

## F.45.5. Session Audit Logging

Session audit logging provides detailed logs of all statements executed by a user in the backend.

### F.45.5.1. Configuration

Session logging is enabled with the `ltaudit.log` setting.

Enable session logging for all DML and DDL and log all relations in DML statements:

```
set ltaudit.log = 'write, ddl';
set ltaudit.log_relation = on;
```

Enable session logging for all commands except MISC and raise audit log messages as NOTICE:

```
set ltaudit.log = 'all, -misc';
set ltaudit.log_level = notice;
```

### F.45.5.2. Example

In this example session audit logging is used for logging DDL and SELECT statements. Note that the insert statement is not logged since the WRITE class is not enabled

*SQL:*

```
set ltaudit.log = 'read, ddl';

create table account
(
    id int,
    name text,
    password text,
    description text
);

insert into account (id, name, password, description)
values (1, 'user1', 'HASH1', 'blah, blah');

select *
from account;
```

*Log Output:*

```
AUDIT: SESSION,1,1,DDL,CREATE TABLE,TABLE,public.account,create
table account
(
    id int,
    name text,
    password text,
    description text
);,<not logged>
AUDIT: SESSION,2,1,READ,SELECT,,,select *
from account,,<not logged>
```

## F.45.6. Object Audit Logging

Object audit logging logs statements that affect a particular relation. Only `SELECT`, `INSERT`, `UPDATE` and `DELETE` commands are supported. `TRUNCATE` is not included in object audit logging.

Object audit logging is intended to be a finer-grained replacement for `ltaudit.log = 'read, write'`. As such, it may not make sense to use them in conjunction but one possible scenario would be to use session logging to capture each statement and then supplement that with object logging to get more detail about specific relations.

### F.45.6.1. Configuration

Object-level audit logging is implemented via the roles system. The `ltaudit.role` setting defines the role that will be used for audit logging. A relation (`TABLE`, `VIEW`, etc.) will be audit logged when the audit role has permissions for the command executed or inherits the permissions from another role. This allows you to effectively have multiple audit roles even though there is a single master role in any context.

Set `ltaudit.role` to `auditor` and grant `SELECT` and `DELETE` privileges on the `account` table. Any `SELECT` or `DELETE` statements on the `account` table will now be logged:

```
set ltaudit.role = 'auditor';

grant select, delete
  on public.account
  to auditor;
```

### F.45.6.2. Example

In this example object audit logging is used to illustrate how a granular approach may be taken towards logging of `SELECT` and DML statements. Note that logging on the `account` table is controlled by column-level permissions, while logging on the `account_role_map` table is table-level.

*SQL:*

```
set ltaudit.role = 'auditor';

create table account
(
  id int,
  name text,
  password text,
  description text
);

grant select (password)
  on public.account
  to auditor;

select id, name
  from account;

select password
  from account;

grant update (name, password)
```

```
    on public.account
    to auditor;

update account
    set description = 'yada, yada';

update account
    set password = 'HASH2';

create table account_role_map
(
    account_id int,
    role_id int
);

grant select
    on public.account_role_map
    to auditor;

select account.password,
       account_role_map.role_id
from account
     inner join account_role_map
       on account.id = account_role_map.account_id
```

*Log Output:*

```
AUDIT: OBJECT,1,1,READ,SELECT,TABLE,public.account,select password
       from account,<not logged>
AUDIT: OBJECT,2,1,WRITE,UPDATE,TABLE,public.account,update account
       set password = 'HASH2',<not logged>
AUDIT: OBJECT,3,1,READ,SELECT,TABLE,public.account,select
       account.password,
       account_role_map.role_id
       from account
       inner join account_role_map
         on account.id = account_role_map.account_id,<not
logged>
AUDIT: OBJECT,3,1,READ,SELECT,TABLE,public.account_role_map,select
       account.password,
       account_role_map.role_id
       from account
       inner join account_role_map
         on account.id = account_role_map.account_id,<not
logged>
```

## F.45.7. Format

Audit entries are written to the standard logging facility and contain the following columns in comma-separated format. Output is compliant CSV format only if the log line prefix portion of each log entry is removed.

- **AUDIT\_TYPE** - SESSION or OBJECT.
- **STATEMENT\_ID** - Unique statement ID for this session. Each statement ID represents a backend call. Statement IDs are sequential even if some statements are not logged. There may be multiple entries for a statement ID when more than one relation is logged.

- **SUBSTATEMENT\_ID** - Sequential ID for each sub-statement within the main statement. For example, calling a function from a query. Sub-statement IDs are continuous even if some sub-statements are not logged. There may be multiple entries for a sub-statement ID when more than one relation is logged.
- **CLASS** - e.g. READ, ROLE (see `ltaudit.log`).
- **COMMAND** - e.g. ALTER TABLE, SELECT.
- **OBJECT\_TYPE** - TABLE, INDEX, VIEW, etc. Available for SELECT, DML and most DDL statements.
- **OBJECT\_NAME** - The fully-qualified object name (e.g. public.account). Available for SELECT, DML and most DDL statements.
- **STATEMENT** - Statement executed on the backend.
- **PARAMETER** - If `ltaudit.log_parameter` is set then this field will contain the statement parameters as quoted CSV or <none> if there are no parameters. Otherwise, the field is <not logged>.

Use `log_line_prefix` to add any other fields that are needed to satisfy your audit log requirements. A typical log line prefix might be `'%m %u %d [%p]: '` which would provide the date/time, user name, database name, and process id for each audit log.

## F.45.8. Caveats

Object renames are logged under the name they were renamed to. For example, renaming a table will produce the following result:

```
ALTER TABLE test RENAME TO test2;
```

```
AUDIT: SESSION,36,1,DDL,ALTER TABLE,TABLE,public.test2,ALTER TABLE  
test RENAME TO test2,<not logged>
```

It is possible to have a command logged more than once. For example, when a table is created with a primary key specified at creation time the index for the primary key will be logged independently and another audit log will be made for the index under the create entry. The multiple entries will however be contained within one statement ID.

Autovacuum and Autoanalyze are not logged.

Statements that are executed after a transaction enters an aborted state will not be audit logged. However, the statement that caused the error and any subsequent statements executed in the aborted transaction will be logged as ERRORS by the standard logging facility.

## F.46. Itcrypto

The `ltpcrypto` module provides cryptographic functions for LightDB.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

### F.46.1. General Hashing Functions

#### F.46.1.1. `digest()`

`digest(data text, type text)` returns `bytea`

`digest(data bytea, type text)` returns `bytea`

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. If `ltdcrypto` was built with `OpenSSL`, more algorithms are available, as detailed in Table F.61.

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

### F.46.1.2. `hmac()`

`hmac(data text, key text, type text)` returns `bytea`

`hmac(data bytea, key bytea, type text)` returns `bytea`

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

## F.46.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F.58 lists the algorithms supported by the `crypt()` function.

**Table F.58. Supported Algorithms for `crypt()`**

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
<code>bf</code>	72	yes	128	60	Blowfish-based, variant 2a
<code>md5</code>	unlimited	no	48	34	MD5-based <code>crypt</code>
<code>xdes</code>	8	yes	24	20	Extended DES

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
des	8	no	12	13	Original UNIX crypt

### F.46.2.1. crypt ( )

`crypt(password text, salt text)` returns `text`

Calculates a crypt(3)-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch
FROM ... ;
```

This returns `true` if the entered password is correct.

### F.46.2.2. gen\_salt ( )

`gen_salt(type text [, iter_count integer ])` returns `text`

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The *iter\_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *iter\_count* parameter is omitted, the default iteration count is used. Allowed values for *iter\_count* depend on the algorithm and are shown in Table F.59.

**Table F.59. Iteration Counts for crypt ( )**

Algorithm	Default	Min	Max
xdes	725	1	16777215
bf	6	4	31

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F.60 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming

that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the `iter_count` parameter of `gen_salt`.

**Table F.60. Hash Algorithm Speeds**

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
<code>crypt-bf/8</code>	1792	4 years	3927 years	100k
<code>crypt-bf/7</code>	3648	2 years	1929 years	50k
<code>crypt-bf/6</code>	7168	1 year	982 years	25k
<code>crypt-bf/5</code>	13504	188 days	521 years	12.5k
<code>crypt-md5</code>	171584	15 days	41 years	1k
<code>crypt-des</code>	23221568	157.5 minutes	108 days	7
<code>sha1</code>	37774272	90 minutes	68 days	4
<code>md5 (hash)</code>	150085504	22.5 minutes	17 days	1

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5 hash` numbers are from `mdcrack 1.2`.
- `sha1` numbers are from `lcrack-20031130-beta`.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `ltcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

## F.46.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.

3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. An SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

### F.46.3.1. `pgp_sym_encrypt ( )`

```
pgp_sym_encrypt(data text, psw text [, options text ]) returns
bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ])
returns bytea
```

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

### F.46.3.2. `pgp_sym_decrypt ( )`

```
pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ])
returns bytea
```

Decrypt a symmetric-key-encrypted PGP message.

Decrypting *bytea* data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

### F.46.3.3. `pgp_pub_encrypt ( )`

```
pgp_pub_encrypt(data text, key bytea [, options text ]) returns
bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ])
returns bytea
```

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

### F.46.3.4. `pgp_pub_decrypt ( )`

```
pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options
text ]]) returns text
```

```
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options
text ]]) returns bytea
```

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting *bytea* data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

### F.46.3.5. `pgp_key_id()`

```
pgp_key_id(bytea) returns text
```

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `lscrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

### F.46.3.6. `armor()`, `dearmor()`

```
armor(data bytea [, keys text[], values text[] ]) returns text
dearmor(data text) returns bytea
```

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *keys* and *values* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

### F.46.3.7. `pgp_armor_headers`

```
pgp_armor_headers(data text, key out text, value out text) returns
setof record
```

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

### F.46.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

#### **F.46.3.8.1. cipher-algo**

Which cipher algorithm to use.

Values: `bf`, `aes128`, `aes192`, `aes256` (OpenSSL-only: `3des`, `cast5`)

Default: `aes128`

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### **F.46.3.8.2. compress-algo**

Which compression algorithm to use. Only available if LightDB was built with `zlib`.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### **F.46.3.8.3. compress-level**

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### **F.46.3.8.4. convert-crlf**

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`, `pgp_sym_decrypt`, `pgp_pub_decrypt`

#### **F.46.3.8.5. disable-mdc**

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent `gnupg.org` and `pgp.com` software supports it fine.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### **F.46.3.8.6. sess-key**

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1  
Default: 0  
Applies to: pgp\_sym\_encrypt

#### **F.46.3.8.7. s2k-mode**

Which S2K algorithm to use.

Values:  
0 - Without salt. Dangerous!  
1 - With salt but with fixed iteration count.  
3 - Variable iteration count.  
Default: 3  
Applies to: pgp\_sym\_encrypt

#### **F.46.3.8.8. s2k-count**

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952  
Applies to: pgp\_sym\_encrypt, only with s2k-mode=3

#### **F.46.3.8.9. s2k-digest-algo**

Which digest algorithm to use in S2K calculation.

Values: md5, sha1  
Default: sha1  
Applies to: pgp\_sym\_encrypt

#### **F.46.3.8.10. s2k-cipher-algo**

Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256  
Default: use cipher-algo  
Applies to: pgp\_sym\_encrypt

#### **F.46.3.8.11. unicode-mode**

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1  
Default: 0  
Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt

### F.46.3.9. Generating PGP Keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, The GNU Privacy Handbook<sup>4</sup> and other documentation on <https://www.gnupg.org/>.

### F.46.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `lscrypto`, but create new ones, as the usage scenario is rather different.

## F.46.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

---

<sup>4</sup> <https://www.gnupg.org/gph/en/manual.html>

`encrypt(data bytea, key bytea, type text)` returns `bytea`  
`decrypt(data bytea, key bytea, type text)` returns `bytea`

`encrypt_iv(data bytea, key bytea, iv bytea, type text)` returns `bytea`  
`decrypt_iv(data bytea, key bytea, iv bytea, type text)` returns `bytea`

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where *algorithm* is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- `cbc` — next block depends on previous (default)
- `ecb` — each block is encrypted separately (for testing only)

and *padding* is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')  
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the *iv* parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

## F.46.5. Random-Data Functions

`gen_random_bytes(count integer)` returns `bytea`

Returns *count* cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

`gen_random_uuid()` returns `uuid`

Returns a version 4 (random) UUID. (Obsolete, this function is now also included in core LightDB.)

## F.46.6. Notes

### F.46.6.1. Configuration

`ltdcrypto` configures itself according to the findings of the main LightDB `configure` script. The options that affect it are `--with-zlib` and `--with-openssl`.

When compiled with zlib, PGP encryption functions are able to compress data before encrypting.

When compiled with OpenSSL, there will be more algorithms available. Also public-key encryption functions will be faster as OpenSSL has more optimized BIGNUM functions.

**Table F.61. Summary of Functionality with and without OpenSSL**

Functionality	Built-in	With OpenSSL
MD5	yes	yes
SHA1	yes	yes
SHA224/256/384/512	yes	yes
Other digest algorithms	no	yes (Note 1)
Blowfish	yes	yes
AES	yes	yes
DES/3DES/CAST5	no	yes
Raw encryption	yes	yes
PGP Symmetric encryption	yes	yes
PGP Public-Key encryption	yes	yes

When compiled against OpenSSL 3.0.0 and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

Notes:

1. Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

### F.46.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

### F.46.6.3. Security Limitations

All `lcrypto` functions run inside the database server. That means that all the data and passwords move between `lcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist side-channel attacks<sup>5</sup>. For example, the time required for a `lcrypto` decryption function to complete varies among ciphertexts of a given size.

### F.46.6.4. Useful Reading

- <https://www.gnupg.org/gph/en/manual.html>

The GNU Privacy Handbook.

- <https://www.openwall.com/crypt/>

Describes the crypt-blowfish algorithm.

### F.46.7. Author

Marko Kreen <markokr@gmail.com>

`libcrypto` uses code from the following sources:

Algorithm	Author	Source origin
DES crypt	David Burren and others	FreeBSD libcrypt
MD5 crypt	Poul-Henning Kamp	FreeBSD libcrypt
Blowfish crypt	Solar Designer	www.openwall.com
Blowfish cipher	Simon Tatham	PuTTY
Rijndael cipher	Brian Gladman	OpenBSD sys/crypto
MD5 hash and SHA1	WIDE Project	KAME kame/sys/crypto
SHA256/384/512	Aaron D. Gifford	OpenBSD sys/crypto
BIGNUM math	Michael J. Fromberger	dartmouth.edu/~sting/sw/imath

### F.47. Itfce

`libfce` - All mode's compatibility functions and operators.

## F.47.1. Features Compatible with all mode

Features compatible with all mode are provided. Functions and operators are created under `lt_catalog`. The table below lists features that can be used in all mode.

**Table F.62. Functions**

Item	Overview
DATABASE	Return current schema as current database
LOCATE	Return the position of the substring in the string

**Table F.63. Operator type compatibility**

Item
LEFTARG:int2 RIGHTARG:text
LEFTARG:int4 RIGHTARG:text
LEFTARG:int8 RIGHTARG:text
LEFTARG:text RIGHTARG:int2
LEFTARG:text RIGHTARG:int4
LEFTARG:text RIGHTARG:int8
LEFTARG:text RIGHTARG:numeric
LEFTARG:numeric RIGHTARG:text

## F.47.2. Functions

- DATABASE
- LOCATE

### F.47.2.1. DATABASE

#### Description

Synonym for `current_schema()`. The concept of schema is similar to that of database in MySQL. You can specify the current schema by setting the `search_path`.

#### Syntax

```
database() RETURNS text
```

#### General rules

- Returns the name of the schema that is first in the search path (or a null value if the search path is empty).
- Like mysql, This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

#### Example

```
lightdb@lt_test=# select database();
database
```

```

-----
public
(1 row)

```

## F.47.2.2. LOCATE

### Description

Return the position of the first occurrence of substring.

### Syntax

```

LOCATE(substr TEXT,str TEXT) returns INTEGER
LOCATE(substr TEXT,str TEXT,POS INTEGER) returns INTEGER

```

### General rules

- The first syntax returns the position of the first occurrence of substring *substr* in string *str*.
- The second syntax returns the position of the first occurrence of substring *substr* in string *str*, starting at position *pos*.
- Returns 0 if *substr* is not in *str*.
- Returns NULL if any argument is NULL.

### Example

In the following example, position of 'bar' in 'foobarbar', starting at position 5. is returned.

```

SELECT LOCATE('bar', 'foobarbar', 5);
   locate
-----
        7
(1 row)

```

## F.47.3. Operator type compatibility

Add type overloading between text and Numeric Types(int2, int4, int8, numeric) for operators such as '+', '-', '\*', '/', '<', '<=', '>', '>=', '=', '<>' and '%'.

### Example

With it, you can directly add '1.1'::text with 1.

```

lightdb@test=# select '1.1'::text+1;
 ?column?
-----
        2.1
(1 row)

```

When in Oracle or MySQL compatible type (see `lightdb_syntax_compatible_type`), base on the rule that 'unknown' can convert to 'text' in some situations (see Chapter 10 for details), you can directly add '1.1' with 1.

```
lightdb@test=# select '1.1'+1;
?column?
-----
      2.1
(1 row)
```

## F.48. Itfincore

A set of functions to manage pages in memory from LightDB

A set of functions to handle low-level management of relations using mincore to explore cache memory.

### F.48.1. DESCRIPTION

With LightDB, each Table or Index is splitted in segments of (usually) 1GB, and each segment is splitted in pages in memory then in blocks for the filesystem.

Those functions let you know which and how many disk block from a relation are in the page cache of the operating system. It can provide the result as a VarBit and can be stored in a table. Then using this table, it is possible to restore the page cache state for each block of the relation, even in another server, thanks to Streaming Replication.

Other functions are used to set a *POSIX\_FADVISE* flag on the entire relation (each segment). The more usefull are probably *WILLNEED* and *DONTNEED* which push and pop blocks of each segments of a relation from page cache, respectively.

Each functions are call with at least a table name or an index name (or oid) as a parameter and walk each segment of the relation.

### F.48.2. EXAMPLES

Here are some examples of usage. If you want more details go to Documentation\_

#### F.48.2.1. Get current state of a relation

May be useful:

```
cedric=# select * from pgfincore('ltbench_accounts');
   relpath        | segment | os_page_size | rel_os_pages |
pages_mem | group_mem | os_pages_free | databit | pages_dirty |
group_dirty
-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
base/11874/16447  |         0 |          4096 |          262144 |
262144 |         1 |          81016 |              |             0 |
0
base/11874/16447.1 |         1 |          4096 |          65726 |
65726 |         1 |          81016 |              |             0 |
0
(2 rows)
```

Time: 31.563 ms

### F.48.2.2. Load a table or an index in OS Page Buffer

You may want to try to keep a table or an index into the OS Page Cache, or preload a table before your well know big query is executed (reducing the query time).

To do so, just execute the following query:

```
cedric=# select * from pgfadvise_willneed('ltbench_accounts');
      relpath          | os_page_size | rel_os_pages | os_pages_free
-----+-----+-----+-----
 base/11874/16447     |          4096 |          262144 |          169138
 base/11874/16447.1 |          4096 |           65726 |          103352
(2 rows)
```

Time: 4462,936 ms

- The column *os\_page\_size* report that page size is 4KB.
- The column *rel\_os\_pages* is the number of pages of the specified file.
- The column *os\_pages\_free* is the number of free pages in memory (for caching).

### F.48.2.3. Snapshot and Restore the OS Page Buffer state of a table or an index (or more)

You may want to restore a table or an index into the OS Page Cache as it was while you did the snapshot. For example if you have to reboot your server, then when LightDB start up the first queries might be slower because neither LightDB or the OS have pages in their respective cache about the relations involved in those first queries.

Executing a snapshot and a restore is very simple:

```
-- Snapshot
cedric=# create table pgfincore_snapshot as
cedric=# select 'ltbench_accounts'::text as relname,*,now() as
date_snapshot
cedric=# from pgfincore('ltbench_accounts',true);

-- Restore
cedric=# select * from pgfadvise_loader('ltbench_accounts', 0,
true, true,
(select databit from pgfincore_snapshot
where relname='ltbench_accounts' and
segment = 0));
      relpath          | os_page_size | os_pages_free | pages_loaded |
pages_unloaded
-----+-----+-----+-----+-----
 base/11874/16447     |          4096 |          80867 |          262144 |
0
(1 row)
```

Time: 35.349 ms

- The column *pages\_loaded* report how many pages have been read to memory (they may have already been in memoy)

- The column *pages\_unloaded* report how many pages have been removed from memory (they may not have already been in memoy);

## F.48.3. SYNOPSIS

`pgsysconf(OUT os_page_size bigint, OUT os_pages_free bigint, OUT os_total_pages bigint)`  
RETURNS record

`pgsysconf_pretty(OUT os_page_size text, OUT os_pages_free text, OUT os_total_pages text)`  
RETURNS record

`pgfadvise(IN relname regclass, IN fork text, IN action int, OUT relpath text, OUT os_page_size bigint, OUT rel_os_pages bigint, OUT os_pages_free bigint)` RETURNS setof record

`pgfadvise_willneed(IN relname regclass, OUT relpath text, OUT os_page_size bigint, OUT rel_os_pages bigint, OUT os_pages_free bigint)` RETURNS setof record

`pgfadvise_dontneed(IN relname regclass, OUT relpath text, OUT os_page_size bigint, OUT rel_os_pages bigint, OUT os_pages_free bigint)` RETURNS setof record

`pgfadvise_normal(IN relname regclass, OUT relpath text, OUT os_page_size bigint, OUT rel_os_pages bigint, OUT os_pages_free bigint)` RETURNS setof record

`pgfadvise_sequential(IN relname regclass, OUT relpath text, OUT os_page_size bigint, OUT rel_os_pages bigint, OUT os_pages_free bigint)` RETURNS setof record

`pgfadvise_random(IN relname regclass, OUT relpath text, OUT os_page_size bigint, OUT rel_os_pages bigint, OUT os_pages_free bigint)` RETURNS setof record

`pgfadvise_loader(IN relname regclass, IN fork text, IN segment int, IN load bool, IN unload bool, IN databit varbit, OUT relpath text, OUT os_page_size bigint, OUT os_pages_free bigint, OUT pages_loaded bigint, OUT pages_unloaded bigint)` RETURNS setof record

`pgfadvise_loader(IN relname regclass, IN segment int, IN load bool, IN unload bool, IN databit varbit, OUT relpath text, OUT os_page_size bigint, OUT os_pages_free bigint, OUT pages_loaded bigint, OUT pages_unloaded bigint)` RETURNS setof record

`pgfincore(IN relname regclass, IN fork text, IN getdatabit bool, OUT relpath text, OUT segment int, OUT os_page_size bigint, OUT rel_os_pages bigint, OUT pages_mem bigint, OUT group_mem bigint, OUT os_pages_free bigint, OUT databit varbit, OUT pages_dirty bigint, OUT group_dirty bigint)` RETURNS setof record

`pgfincore(IN relname regclass, IN getdatabit bool, OUT relpath text, OUT segment int, OUT os_page_size bigint, OUT rel_os_pages bigint, OUT pages_mem bigint, OUT group_mem bigint, OUT os_pages_free bigint, OUT databit varbit, OUT pages_dirty bigint, OUT group_dirty bigint)` RETURNS setof record

`pgfincore(IN relname regclass, OUT relpath text, OUT segment int, OUT os_page_size bigint, OUT rel_os_pages bigint, OUT pages_mem bigint, OUT group_mem bigint, OUT os_pages_free bigint, OUT databit varbit, OUT pages_dirty bigint, OUT group_dirty bigint)` RETURNS setof record

## F.48.4. DOCUMENTATION

### F.48.4.1. pgsysconf

This function output size of OS blocks, number of free page in the OS Page Buffer.

```
cedric=# select * from pgsysconf();
 os_page_size | os_pages_free | os_total_pages
-----+-----+-----
          4096 |          80431 |          4094174
```

#### F.48.4.2. pgsysconf\_pretty

The same as above, but with pretty output.

```
cedric=# select * from pgsysconf_pretty();
 os_page_size | os_pages_free | os_total_pages
-----+-----+-----
4096 bytes   | 314 MB       | 16 GB
```

#### F.48.4.3. pgfadvise\_WILLNEED

This function set *WILLNEED* flag on the current relation. It means that the Operating System will try to load as much pages as possible of the relation. Main idea is to preload files on server startup, perhaps using cache hit/miss ratio or most required relations/indexes.

```
cedric=# select * from pgfadvise_willneed('ltbench_accounts');
 relpath          | os_page_size | rel_os_pages | os_pages_free
-----+-----+-----+-----
base/11874/16447  |          4096 |          262144 |          80650
base/11874/16447.1 |          4096 |           65726 |          80650
```

#### F.48.4.4. pgfadvise\_DONTNEED

This function set *DONTNEED* flag on the current relation. It means that the Operating System will first unload pages of the file if it need to free some memory. Main idea is to unload files when they are not usefull anymore (instead of perhaps more interesting pages)

```
cedric=# select * from pgfadvise_dontneed('ltbench_accounts');
 relpath          | os_page_size | rel_os_pages | os_pages_free
-----+-----+-----+-----
base/11874/16447  |          4096 |          262144 |          342071
base/11874/16447.1 |          4096 |           65726 |          408103
```

#### F.48.4.5. pgfadvise\_NORMAL

This function set *NORMAL* flag on the current relation.

#### F.48.4.6. pgfadvise\_SEQUENTIAL

This function set *SEQUENTIAL* flag on the current relation.

#### F.48.4.7. pgfadvise\_RANDOM

This function set *RANDOM* flag on the current relation.

#### F.48.4.8. pgfadvise\_loader

This function allow to interact directly with the Page Cache. It can be used to load and/or unload page from memory based on a varbit representing the map of the pages to load/unload accordingly.

Work with relation `ltbench_accounts`, segment 0, arbitrary varbit map:

```
-- Loading and Unloading
cedric=# select * from pgfadvise_loader('ltbench_accounts', 0,
    true, true, B'111000');
    relpath      | os_page_size | os_pages_free | pages_loaded |
    pages_unloaded
-----+-----+-----+-----+
+-----+
base/11874/16447 |          4096 |          408376 |           3 |
              3

-- Loading
cedric=# select * from pgfadvise_loader('ltbench_accounts', 0,
    true, false, B'111000');
    relpath      | os_page_size | os_pages_free | pages_loaded |
    pages_unloaded
-----+-----+-----+-----+
+-----+
base/11874/16447 |          4096 |          408370 |           3 |
              0

-- Unloading
cedric=# select * from pgfadvise_loader('ltbench_accounts', 0,
    false, true, B'111000');
    relpath      | os_page_size | os_pages_free | pages_loaded |
    pages_unloaded
-----+-----+-----+-----+
+-----+
base/11874/16447 |          4096 |          408370 |           0 |
              3
```

### F.48.4.9. pgfincore

This function provide information about the file system cache (page cache).

```
cedric=# select * from pgfincore('ltbench_accounts');
    relpath      | segment | os_page_size | rel_os_pages |
    pages_mem | group_mem | os_pages_free | databit | pages_dirty |
    group_dirty
-----+-----+-----+-----+
+-----+
+-----+
base/11874/16447 |         0 |          4096 |          262144 |
  3 |         1 |         408444 |           0 |
  0
base/11874/16447.1 |         1 |          4096 |           65726 |
  0 |         0 |         408444 |           0 |
  0
```

For the specified relation it returns:

- `relpath` : the relation path
- `segment` : the segment number analyzed
- `os_page_size` : the size of one page
- `rel_os_pages` : the total number of pages of the relation

- `pages_mem` : the total number of relation's pages in page cache. (not the shared buffers from LightDB but the OS cache)
- `group_mem` : the number of groups of adjacent `pages_mem`
- `os_page_free` : the number of free page in the OS page cache
- `databit` : the varbit map of the file, because of its size it is useless to output Use `pgfincore("ltbench_accounts",true)` to activate it.
- `pages_dirty` : if `HAVE_FINCORE` constant is define and the platform provides the relevant information, like `pages_mem` but for dirtied pages
- `group_dirty` : if `HAVE_FINCORE` constant is define and the platform provides the relevant information, like `group_mem` but for dirtied pages

## F.48.5. DEBUG

You can debug the `ltfincore` with the following error level: `DEBUG1` and `DEBUG5`.

For example:

```
set client_min_messages TO debug1; -- debug5 is only usefull to
trace each block
```

## F.48.6. REQUIREMENTS

- `ltfincore` needs `mincore()` or `fincore()` and `POSIX_FADVISE`

## F.48.7. LIMITATIONS

- `ltfincore` has a limited mode when `POSIX_FADVISE` is not provided by the platform.

## F.49. Itree

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered "trusted", that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.49.1. Definitions

A *label* is a sequence of alphanumeric characters and underscores (for example, in C locale the characters `A-Za-z0-9_` are allowed). Labels must be less than 256 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

```
foo           Match the exact label path foo
*.foo.*      Match any label path containing the label foo
*.foo        Match any label path whose last label is foo
```

Both star symbols and simple words can be quantified to restrict how many labels they can match:

```
*{n}         Match exactly n labels
*{n,}        Match at least n labels
*{n,m}       Match at least n but not more than m labels
*{,m}        Match at most m labels – same as *{0,m}
foo{n,m}     Match at least n but not more than m occurrences
              of foo
foo{,}       Match any number of occurrences of foo, including
              zero
```

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, { , }) while the default for a non-star item is to match exactly once (that is, {1}).

There are several modifiers that can be put at the end of a non-star lquery item to make it match more than just the exact match:

```
@           Match case-insensitively, for example a@ matches A
*           Match any label with this prefix, for example foo*
              matches foobar
%           Match initial underscore-separated words
```

The behavior of % is a bit complicated. It tries to match words rather than the entire label. For example foo\_bar% matches foo\_bar\_baz but not foo\_barbaz. If combined with \*, prefix matching applies to each word separately, for example foo\_bar%\* matches foo1\_bar2\_baz but not foo1\_br2\_baz.

Also, you can write several possibly-modified non-star items separated with | (OR) to match any of those items, and you can put ! (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of lquery:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
a.  b.      c.      d.      e.
```

This query will match any label path that:

- a. begins with the label Top
- b. and next has zero to two labels before
- c. a label beginning with the case-insensitive prefix sport
- d. then has one or more labels, none of which match football nor tennis
- e. and then ends with a label beginning with Russ or exactly matching Spain.

- ltxtquery represents a full-text-search-like pattern for matching ltree values. An ltxtquery value contains words, possibly with the modifiers @, \*, % at the end; the modifiers

have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```
Europe & Russia*@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

## F.49.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F.64 are available.

**Table F.64. `ltree` Operators**

Operator	Description
<code>ltree @&gt; ltree</code>	<code>boolean</code> Is left argument an ancestor of right (or equal)?
<code>ltree &lt;@ ltree</code>	<code>boolean</code> Is left argument a descendant of right (or equal)?
<code>ltree ~ lquery</code>	<code>boolean</code>
<code>lquery ~ ltree</code>	<code>boolean</code> Does <code>ltree</code> match <code>lquery</code> ?
<code>ltree ? lquery[]</code>	<code>boolean</code>
<code>lquery[] ? ltree</code>	<code>boolean</code> Does <code>ltree</code> match any <code>lquery</code> in array?
<code>ltree @ ltxquery</code>	<code>boolean</code>
<code>ltxquery @ ltree</code>	<code>boolean</code> Does <code>ltree</code> match <code>ltxquery</code> ?
<code>ltree    ltree</code>	<code>ltree</code> Concatenates <code>ltree</code> paths.
<code>ltree    text</code>	<code>ltree</code>
<code>text    ltree</code>	<code>ltree</code> Converts text to <code>ltree</code> and concatenates.
<code>ltree[] @&gt; ltree</code>	<code>boolean</code>
<code>ltree &lt;@ ltree[]</code>	<code>boolean</code> Does array contain an ancestor of <code>ltree</code> ?
<code>ltree[] &lt;@ ltree</code>	<code>boolean</code>
<code>ltree @&gt; ltree[]</code>	<code>boolean</code> Does array contain a descendant of <code>ltree</code> ?

<b>Operator</b>	<b>Description</b>
<code>ltree[] ~ lquery</code> → boolean <code>lquery ~ ltree[]</code> → boolean	Does array contain any path matching <code>lquery</code> ?
<code>ltree[] ? lquery[]</code> → boolean <code>lquery[] ? ltree[]</code> → boolean	Does <code>ltree</code> array contain any path matching any <code>lquery</code> ?
<code>ltree[] @ ltxtquery</code> → boolean <code>ltxtquery @ ltree[]</code> → boolean	Does array contain any path matching <code>ltxtquery</code> ?
<code>ltree[] ?@&gt; ltree</code> → ltree	Returns first array entry that is an ancestor of <code>ltree</code> , or NULL if none.
<code>ltree[] ?&lt;@ ltree</code> → ltree	Returns first array entry that is a descendant of <code>ltree</code> , or NULL if none.
<code>ltree[] ?~ lquery</code> → ltree	Returns first array entry that matches <code>lquery</code> , or NULL if none.
<code>ltree[] ?@ ltxtquery</code> → ltree	Returns first array entry that matches <code>ltxtquery</code> , or NULL if none.

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in Table F.65.

**Table F.65. ltree Functions**

<b>Function</b>	<b>Description</b> <b>Example(s)</b>
<code>subtree ( ltree, start integer, end integer )</code> → ltree	Returns subpath of <code>ltree</code> from position <code>start</code> to position <code>end-1</code> (counting from 0). <code>subtree( 'Top.Child1.Child2', 1, 2 )</code> → Child1
<code>subpath ( ltree, offset integer, len integer )</code> → ltree	Returns subpath of <code>ltree</code> starting at position <code>offset</code> , with length <code>len</code> . If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path. <code>subpath( 'Top.Child1.Child2', 0, 2 )</code> → Top.Child1
<code>subpath ( ltree, offset integer )</code> → ltree	Returns subpath of <code>ltree</code> starting at position <code>offset</code> , extending to end of path. If <code>offset</code> is negative, subpath starts that far from the end of the path. <code>subpath( 'Top.Child1.Child2', 1 )</code> → Child1.Child2
<code>nlevel ( ltree )</code> → integer	Returns number of labels in path. <code>nlevel( 'Top.Child1.Child2' )</code> → 3
<code>index ( a ltree, b ltree )</code> → integer	Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found.

Function	Description	Example(s)
		<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6') → 6</code>
	<code>index(a ltree, b ltree, offset integer) → integer</code> Returns position of first occurrence of <i>b</i> in <i>a</i> , or -1 if not found. The search starts at position <i>offset</i> ; negative <i>offset</i> means start <i>-offset</i> labels from the end of the path.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4) → 9</code>
	<code>text2ltree(text) → ltree</code> Casts <i>text</i> to <i>ltree</i> .	
	<code>ltree2text(ltree) → text</code> Casts <i>ltree</i> to <i>text</i> .	
	<code>lca(ltree [, ltree [, ...]]) → ltree</code> Computes longest common ancestor of paths (up to 8 arguments are supported).	<code>lca('1.2.3', '1.2.3.4.5.6') → 1.2</code>
	<code>lca(ltree[]) → ltree</code> Computes longest common ancestor of paths in array.	<code>lca(array['1.2.3'::ltree, '1.2.3.4']) → 1.2</code>

## F.49.3. Indexes

*ltree* supports several types of indexes that can speed up the indicated operators:

- B-tree index over *ltree*: <, <=, =, >=, >
- GiST index over *ltree* (`gist_ltree_ops` opclass): <, <=, =, >=, >, @>, <@, @, ~, ?

`gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path
gist_ltree_ops(siglen=100));
```

- GiST index over *ltree[]* (`gist__ltree_ops` opclass): *ltree[]* <@ *ltree*, *ltree* @> *ltree[]*, @, ~, ?

`gist__ltree_ops` GiST opclass works similarly to `gist_ltree_ops` and also takes signature length as a parameter. The default value of `siglen` in `gist__ltree_ops` is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path
gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

## F.49.4. Example

This example uses the following data (also available in file contrib/ltree/ltreetest.sql in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES
('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES
('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES
('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table test populated with data describing the hierarchy shown below:

```

              Top
             /  |  \
          Science Hobbies Collections
           /      |      \
        Astronomy Amateurs_Astronomy Pictures
         /  \      |
    Astrophysics Cosmology           Astronomy
                                     /  |  \
                                   Galaxies Stars Astronauts
```

We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
           path
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
```

(4 rows)

Here are some examples of path matching:

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path ~ '.*!
pictures@.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !
pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !
pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2) || 'Space' || subpath(path,2) FROM
test WHERE path <@ 'Top.Science.Astronomy';
           ?column?
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating a SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;

ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path
<@ 'Top.Science.Astronomy';
           ins_label
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

## F.49.5. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

## F.50. Itrowlocks

The `ltrowlocks` module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, members of the `pg_stat_scan_tables` role, and users with `SELECT` permissions on the table.

### F.50.1. Overview

`pgrowlocks(text)` returns `setof record`

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F.66.

**Table F.66. `pgrowlocks` Output Columns**

Name	Type	Description
<code>locked_row</code>	<code>tid</code>	Tuple ID (TID) of locked row
<code>locker</code>	<code>xid</code>	Transaction ID of locker, or multixact ID if multitransaction
<code>multi</code>	<code>boolean</code>	True if locker is a multitransaction
<code>xids</code>	<code>xid[]</code>	Transaction IDs of lockers (more than one if multitransaction)
<code>modes</code>	<code>text[]</code>	Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.

Name	Type	Description
<code>pids</code>	<code>integer[]</code>	Process IDs of locking backends (more than one if multitransaction)

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

## F.50.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids | modes | pids
-----+-----+-----+-----+-----+-----
(0,1)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,2)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,3)      | 607   | f     | {607} | {"For Update"} | {3107}
(0,4)      | 607   | f     | {607} | {"For Update"} | {3107}
(4 rows)
```

## F.50.3. Author

Tatsuo Ishii

## F.51. Itstattuple

The `ltstattuple` module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has `EXECUTE` privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

### F.51.1. Functions

`pgstattuple(regclass)` returns record

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
```

```

-[ RECORD 1 ]-----+-----
table_len      | 458752
tuple_count    | 1470
tuple_len      | 438896
tuple_percent  | 95.67
dead_tuple_count | 11
dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space     | 8932
free_percent   | 1.95

```

The output columns are described in Table F.67.

**Table F.67. pgstattuple Output Columns**

Column	Type	Description
table_len	bigint	Physical relation length in bytes
tuple_count	bigint	Number of live tuples
tuple_len	bigint	Total length of live tuples in bytes
tuple_percent	float8	Percentage of live tuples
dead_tuple_count	bigint	Number of dead tuples
dead_tuple_len	bigint	Total length of dead tuples in bytes
dead_tuple_percent	float8	Percentage of dead tuples
free_space	bigint	Total free space in bytes
free_percent	float8	Percentage of free space

### Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```

test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----

```

```

version          | 2
tree_level      | 0
index_size      | 16384
root_block_no   | 1
internal_pages  | 0
leaf_pages      | 1
empty_pages     | 0
deleted_pages   | 0
avg_leaf_density| 54.27
leaf_fragmentation | 0
    
```

The output columns are:

Column	Type	Description
version	integer	B-tree version number
tree_level	integer	Tree level of the root page
index_size	bigint	Total index size in bytes
root_block_no	bigint	Location of root page (zero if none)
internal_pages	bigint	Number of "internal" (upper-level) pages
leaf_pages	bigint	Number of leaf pages
empty_pages	bigint	Number of empty pages
deleted_pages	bigint	Number of deleted pages
avg_leaf_density	float8	Average density of leaf pages
leaf_fragmentation	float8	Leaf page fragmentation

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages` + `leaf_pages` + `empty_pages` + `deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```

test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]---
version          | 1
pending_pages    | 0
pending_tuples   | 0
    
```

The output columns are:

Column	Type	Description
version	integer	GIN version number

Column	Type	Description
pending_pages	integer	Number of pages in the pending list
pending_tuples	bigint	Number of tuples in the pending list

pgstathashindex(regclass) returns record

pgstathashindex returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]-----+-----
version          | 4
bucket_pages    | 33081
overflow_pages  | 0
bitmap_pages    | 1
unused_pages    | 32455
live_items      | 10204006
dead_items      | 0
free_percent    | 61.8005949100872
```

The output columns are:

Column	Type	Description
version	integer	HASH version number
bucket_pages	bigint	Number of bucket pages
overflow_pages	bigint	Number of overflow pages
bitmap_pages	bigint	Number of bitmap pages
unused_pages	bigint	Number of unused pages
live_items	bigint	Number of live tuples
dead_tuples	bigint	Number of dead tuples
free_percent	float	Percentage of free space

pg\_relpages(regclass) returns bigint

pg\_relpages returns the number of pages in the relation.

pg\_relpages(text) returns bigint

This is the same as pg\_relpages(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstattuple\_approx(regclass) returns record

pgstattuple\_approx is a faster alternative to pgstattuple that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM
  pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----+-----
table_len          | 573440
scanned_percent    | 2
```

```

approx_tuple_count    | 2740
approx_tuple_len      | 561210
approx_tuple_percent  | 97.87
dead_tuple_count      | 0
dead_tuple_len        | 0
dead_tuple_percent    | 0
approx_free_space     | 11996
approx_free_percent   | 2.09

```

The output columns are described in Table F.68.

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that `VACUUM` estimates `pg_class.reltuples`).

**Table F.68. `pgstattuple_approx` Output Columns**

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes (exact)
<code>scanned_percent</code>	<code>float8</code>	Percentage of table scanned
<code>approx_tuple_count</code>	<code>bigint</code>	Number of live tuples (estimated)
<code>approx_tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes (estimated)
<code>approx_tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples (exact)
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes (exact)
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>approx_free_space</code>	<code>bigint</code>	Total free space in bytes (estimated)
<code>approx_free_percent</code>	<code>float8</code>	Percentage of free space

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

## F.51.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

## F.52. `It_walminer`

## F.52.1. What is It\_walminer?

Please refer to the It\_walminer reference manual<sup>6</sup>.

## F.53. myfce

myfce - Mysql's compatibility functions.

### F.53.1. Features Compatible with Mysql Databases

Features compatible with Mysql databases are provided. These features enable you to easily migrate to LightDB and reduce the costs of reconfiguring applications. The table below lists features compatible with Mysql databases.

**Table F.69. Data type**

Item	Overview
DATETIME	DATETIME is an alias for timestamp without time zone.
LONGTEXT	LONGTEXT is an alias for TEXT.
SIGNED	SIGNED is a signed integer, equivalent to bigint.

**Table F.70. Data Cast**

Item	Overview
bool->varchar	Transform bool type true to string '1' and false to string '0' for compatible with mysql
cast(expr as unsigned)	Transform expr to unsigned bigint value, but now return type is numeric.

**Table F.71. Mathematical Functions**

Item	Overview
CONV	Convert numbers between different number bases
LOG10	Return the base-10 logarithm of the argument
LOG2	Return the base-2 logarithm of the argument
RAND	Returns a random floating-point value v in the range 0 and 1.0
TRUNCATE	Truncate to specified number of decimal places

**Table F.72. String Functions**

Item	Overview
ELT	Return string at index number
FIELD	Index (position) of first argument in subsequent arguments
FIND_IN_SET	Index (position) of first argument within second argument
FROM_BASE64	Decode base64 encoded string and return result

<sup>6</sup> [https://gitee.com/zhjh256/It\\_walminer/blob/master/README.md](https://gitee.com/zhjh256/It_walminer/blob/master/README.md)

Item	Overview
INSERT	Insert substring at specified position up to specified number of characters
INSTR	Get the first occurrence position of the substring
LCASE	Synonym for LOWER()
LOCATE	Return the position of the first occurrence of substring
MID	Return a substring starting from the specified position
SPACE	Return a string of the specified number of spaces
STRCMP	Compare two strings
TO_BASE64	Return the argument converted to a base-64 string
UCASE	Synonym for UPPER()
SUBSTR	Return the substring as specified
SUBSTRING	Return the substring as specified
SUBSTRING_INDEX	Return a substring from a string before the specified number of occurrences of the delimiter

**Table F.73. Date/Time Functions**

Item	Overview
DATEDIFF	Subtract two dates
DATE_ADD	Add the specified time interval to the date
DATE_FORMAT	Return date / time data in different formats
DATE_SUB	Subtracts the specified time interval from the date
DAY	Returns the date part of the date month
DAYOFWEEK	Returns the day of the week index of the current week, starting at 1
FROM_UNIXTIME	Returns the date / datetime representation of the UNIX timestamp
SEC_TO_TIME	Converts seconds to 'hh:mm:ss' format
STR_TO_DATE	Convert string to date / time value
SYSDATE	Return the time at which the function executes
TIME_TO_SEC	Return the argument converted to seconds
TIMEDIFF	Subtract time
TIMESTAMPDIFF	Subtract an interval from a datetime expression
TO_DAYS	Return the date argument converted to days
TO_SECONDS	Return the date or datetime argument converted to seconds since Year 0
UNIX_TIMESTAMP	Returns the UNIX timestamp of an exact point in time
WEEKOFYEAR	Returns the number of weeks of the date
YEAR	Returns the year of the date
QUARTER	Returns the quarter of the year for date

Item	Overview
LAST_DAY	Return the last day of the month for the argument
CURDATE	Return the current date

**Table F.74. JSON Functions**

Item	Overview
JSON_ARRAY	Evaluates a (possibly empty) list of values and returns a JSON array containing those values.
JSON_OBJECT	Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs.
JSON_EXTRACT	Returns data from a JSON document, selected from the parts of the document matched by the path arguments.
JSON_CONTAINS	Indicates by returning true or false whether a given candidate JSON document is contained within a target JSON document.
JSON_CONTAINS_PATH	Returns true or false to indicate whether a JSON document contains data at a given path or paths.
JSON_PRETTY	Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems.
JSON_REMOVE	Removes data from a JSON document and returns the result.
JSON_INSERT	Inserts data into a JSON document and returns the result.
JSON_REPLACE	Replaces existing values in a JSON document and returns the result.
JSON_SET	Inserts or updates data in a JSON document and returns the result.

**Table F.75. Conditional Expressions**

Item	Overview
IF	If/else construct

**Table F.76. Aggregate Functions**

Item	Overview
ANY_VALUE	For compatibility with MySQL mode non ONLY_FULL_GROUP_BY syntax behavior of group by in by mode
GROUP_CONCAT	Returns a concatenated, delimited list of string values.

**Table F.77. System Information Functions and Operators**

Item	Overview
DATABASE	Synonym for current_schema()

**Table F.78. Miscellaneous Functions**

Item	Overview
BIN_TO_UUID	Convert binary UUID to string
COMPRESS	Compress string and return binary data
UNCOMPRESS	Decompress the binary data compressed by compress() and restore the original string
UUID	returns a randomly generated UUID, as a string of 36 characters.
UUID_TO_BIN	Convert string UUID to binary

**Table F.79. Operators**

Item	Overview
IFNULL	The corresponding value is returned according to whether the parameter is empty
ISNULL	Test whether the argument is NULL

**Table F.80. Arithmetic Operators**

Item	Overview
/	Division operator

**Table F.81. Compare Operators**

Item	Overview
=	Equal operator, support for varchar with bool or text.
!=	Non-equal operator, support for varchar with bool or text.

**Table F.82. SQL Queries**

Item	Overview
DUAL table	Table provided by the system

## F.53.2. SQL Functions Reference

### F.53.2.1. Mathematical Functions

The following mathematical functions are supported:

- CONV
- LOG10
- LOG2
- RAND
- TRUNCATE

#### F.53.2.1.1. CONV

**Description**

Convert numbers between different number bases.

**Syntax**

```
conv( p_num text, p_from_base int4, p_to_base int4) RETURNS text
```

**General rules**

- Converts numbers between different number bases.
- Returns a string representation of the number N, converted from base from\_base to base to\_base. Returns NULL if any argument is NULL. The argument N is interpreted as an integer, but may be specified as an integer or a string.
- The minimum base is 2 and the maximum base is 36. If from\_base is a negative number, N is regarded as a signed number. Otherwise, N is treated as unsigned. CONV() works with 64-bit precision.

**Example**

In the following example, '123456' converted from base 10 to base 16 is 1E240.

```
select conv('123456', 10, 16);
conv
-----
1E240
(1 row)
```

**F.53.2.1.2. LOG10****Description**

return the base-10 logarithm of the argument.

**Syntax**

```
log10(p1 numeric) RETURNS numeric
log10(p1 double precision) RETURNS double precision
```

**General rules**

- Returns the base-10 logarithm of p1. If X is less than or equal to 0.0E0, the function returns NULL and a warning “Invalid argument for logarithm” is reported.

**Example**

In the following example, return the base-10 logarithm of the argument 2.

```
select log10(2);
log10
-----
0.3010299956639812
(1 row)
```

### F.53.2.1.3. LOG2

**Description**

Return the base-2 logarithm of the argument.

**Syntax**

```
log2(p_num numeric) RETURNS numeric
```

**General rules**

- Returns the base-2 logarithm of p\_num. If p\_num is less than or equal to 0.0E0, the function returns NULL and a warning “Invalid argument for logarithm” is reported.

**Example**

In the following example, return the base-2 logarithm of the argument 64.

```
select log2(64);
       log2
-----
6.0000000000000000
(1 row)
```

### F.53.2.1.4. RAND

**Description**

Returns a random floating-point value v in the range 0 and 1.0.

**Syntax**

```
rand(p_seed int default null) RETURNS double precision
```

**General rules**

- With a constant initializer argument, the seed is initialized once when the statement is prepared, prior to execution.
- With a nonconstant initializer argument (such as a column name), the seed is initialized with the value for each invocation of RAND().
- One implication of this behavior is that for equal argument values, RAND(N) returns the same value each time, and thus produces a repeatable sequence of column values.
- RAND() in a WHERE clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join).

**Example**

In the following example, the sequence of values produced by RAND(123) is the same both places it occurs.

```
select rand(123);
```

```
          rand
-----
0.05425240159967615
(1 row)
```

### F.53.2.1.5. TRUNCATE

#### Description

Truncate to specified number of decimal places.

#### Syntax

```
TRUNCATE(SMALLINT X,INTEGER D) returns INTEGER
TRUNCATE(INTEGER X,INTEGER D) returns INTEGER
TRUNCATE(BIGINT X,INTEGER D) returns BIGINT
TRUNCATE(DOUBLE PRECISION X,INTEGER D) returns DOUBLE PRECISION
TRUNCATE(NUMERIC,INTEGER D) returns NUMERIC
```

#### General rules

- Returns the number X, truncated to D decimal places.
- If D is 0, the result has no decimal point or fractional part.
- D can be negative to cause D digits left of the decimal point of the value X to become zero.

#### Example

In the following example, the result of "1.223" truncated to 1 decimal places is returned.

```
SELECT TRUNCATE(1.223,1);
   truncate
-----
          1.2
(1 row)
```

### F.53.2.2. String Functions

The following string functions are supported:

- ELT
- FIELD
- FIND\_IN\_SET
- INSTR
- FROM\_BASE64
- INSERT
- LCASE
- LOCATE

- MID
- SPACE
- STRCMP
- TO\_BASE64
- UCASE
- SUBSTR
- SUBSTRING
- SUBSTRING\_INDEX

#### F.53.2.2.1. ELT

##### Description

Return string at index number.

##### Syntax

```
elt(str_pos int, VARIADIC strlist text[]) RETURNS text
```

##### General rules

- ELT() returns the str\_pos<sup>th</sup> element of the list of strings: str1 if str\_pos = 1, str2 if str\_pos = 2, and so on.
- Returns NULL if N is less than 1 or greater than the number of arguments.
- ELT() is the complement of FIELD().

##### Example

In the following example, Return 'Bb' at 2.

```
select elt( 2, 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
elt
-----
Bb
(1 row)
```

#### F.53.2.2.2. FIELD

##### Description

Index (position) of first argument in subsequent arguments.

##### Syntax

```
field(str text, VARIADIC strlist text[]) RETURNS bigint
field(str numeric, VARIADIC strlist numeric[]) RETURNS bigint
```

##### General rules

- Returns the index (position) of *str* in the *str1*, *str2*, *str3*, ... list. Returns 0 if *str* is not found.
- If all arguments to `FIELD()` are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.
- If *str* is NULL, the return value is 0 because NULL fails equality comparison with any value. `FIELD()` is the complement of `ELT()`.

**Example**

In the following example, Index (position) of 'Bb' in 'Aa', 'Bb', 'Cc', 'Dd', 'Ff' 2 is returned.

```
select field('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
field
-----
      2
(1 row)
```

**F.53.2.2.3. FIND\_IN\_SET**

**Description**

Index (position) of first argument within second argument.

**Syntax**

```
FIND_IN_SET(str "any",strlist TEXT) returns INTEGER
```

**General rules**

- Returns a value in the range of 1 to N if the string *str* is in the string list *strlist* consisting of N substrings. *strlist* is a string composed of substrings separated by , characters.
- Returns 0 if *str* is not in *strlist* or if *strlist* is the empty string.
- Returns NULL if either argument is NULL. This function does not work properly if the first argument contains a comma (,) character.
- If first argument is not String Types,the first parameter will be converted to string.In other words,find\_in\_set(n,strlist) is equivalent to find\_in\_set(n::text,strlist)
- The data type of the return value is integer.

**Example**

In the following example,position of 'b' within 'a,b,c,d' is returned.

```
SELECT FIND_IN_SET('b', 'a,b,c,d');
find_in_set
-----
          2
(1 row)
```

**F.53.2.2.4. FROM\_BASE64**

**Description**

Decode base64 encoded string and return result.

**Syntax**

```
from_base64(p_str text) RETURNS text
```

**General rules**

- Takes a string encoded with the base-64 encoded rules used by TO\_BASE64() and returns the decoded result as a binary string.
- The result is NULL if the argument is NULL or not a valid base-64 string.
- See the description of TO\_BASE64() for details about the encoding and decoding rules.

**Example**

In the following example, Decode base64 encoded string 'YWJj' and return result 'abc'.

```
select from_base64('YWJj');
from_base64
-----
abc
(1 row)
```

### F.53.2.2.5. INSERT

**Description**

Insert substring at specified position up to specified number of characters.

**Syntax**

```
insert(p_source text, p_pos bigint, p_len bigint, p_replacement
text) RETURNS text
```

**General rules**

- Returns the string str, with the substring beginning at position pos and len characters long replaced by the string newstr.
- Returns the original string if pos is not within the length of the string. Replaces the rest of the string from position pos if len is not within the length of the rest of the string.
- Returns NULL if any argument is NULL.

**Example**

In the following example, Insert substring 'What' at specified position 3 up to specified number 4 of characters.

```
select insert('Quadratic', 3, 4, 'What');
insert
-----
QuWhattic
```

(1 row)

### F.53.2.2.6. INSTR

#### Description

Get the first occurrence position of the substring.

#### Syntax

```
instr(str text, patt text) RETURNS int
```

#### General rules

- Get the first occurrence position of sub string patt in str, starting from 1.
- If not found, return 0.

#### Example

In the following example, the first occurrence of substring '4de' in string 'abc124deff4de' is 6.

```
select instr('abc124deff4de', '4de');
instr
-----
      6
(1 row)
```

### F.53.2.2.7. LCASE

#### Description

Synonym for LOWER().

#### Syntax

```
lcase(p_source text) RETURNS text
```

#### General rules

- LCASE() is a synonym for LOWER().
- Returns the string str with all characters changed to lowercase according to the current character set mapping. The default is utf8mb4.

#### Example

In the following example,Returns the string 'quadratic' with all characters changed to lowercase.

```
select lcase('QuadRatic');
lcase
-----
quadratic
```

(1 row)

### F.53.2.2.8. LOCATE

#### Description

Return the position of the first occurrence of substring.

#### Syntax

```
LOCATE(substr TEXT,str TEXT) returns INTEGER  
LOCATE(substr TEXT,str TEXT,POS INTEGER) returns INTEGER
```

#### General rules

- The first syntax returns the position of the first occurrence of substring *substr* in string *str*.
- The second syntax returns the position of the first occurrence of substring *substr* in string *str*, starting at position *pos*.
- Returns 0 if *substr* is not in *str*.
- Returns NULL if any argument is NULL.

#### Example

In the following example, position of 'bar' in 'foobarbar', starting at position 5. is returned.

```
SELECT LOCATE('bar', 'foobarbar', 5);  
   locate  
-----  
          7  
(1 row)
```

### F.53.2.2.9. MID

#### Description

Return a substring starting from the specified position.

#### Syntax

```
mid(p_source text, p_pos bigint, p_len bigint) RETURNS text
```

#### General rules

- The forms without a len argument return a substring from string *str* starting at position *pos*. The forms with a len argument return a substring len characters long from string *str*, starting at position *pos*.
- It is also possible to use a negative value for *pos*. In this case, the beginning of the substring is *pos* characters from the end of the string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function. A value of 0 for *pos* returns an empty string.

#### Example

In the following example, return a substring 'ongy' starting from the specified position 2.

```
select mid('Hongye', 2, 4);
mid
-----
ongy
(1 row)
```

### F.53.2.2.10. SPACE

#### Description

Return a string of the specified number of spaces.

#### Syntax

```
space(p_num int) RETURNS text
```

#### General rules

- Returns a string consisting of N space characters.

#### Example

In the following example, return a string of the specified number of spaces.

```
select concat('|', space(11), '|');
concat
-----
|           |
(1 row)
```

### F.53.2.2.11. STRCMP

#### Description

Compare two strings.

#### Syntax

```
strcmp(p1 text, p2 text) RETURNS int
```

#### General rules

- STRCMP() returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

#### Example

In the following example, returns -1 the first argument is smaller than the second according to the current sort order.

```
select strcmp('text', 'text2');
strcmp
-----
      -1
(1 row)
```

### F.53.2.2.12. TO\_BASE64

#### Description

Return the argument converted to a base-64 string.

#### Syntax

```
to_base64(p_str text) RETURNS text
```

#### General rules

- Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation.
- If the argument is not a string, it is converted to a string before conversion takes place. The result is NULL if the argument is NULL.
- Base-64 encoded strings can be decoded using the FROM\_BASE64() function.

#### Example

In the following example, return the argument 'abc' converted to a base-64 string 'YWJj'.

```
select to_base64('abc');
to_base64
-----
YWJj
(1 row)
```

### F.53.2.2.13. UCASE

#### Description

Synonym for UPPER().

#### Syntax

```
ucase(p_source text) RETURNS text
```

#### General rules

- Returns the string str with all characters changed to uppercase according to the current character set mapping. The default is utf8mb4.

#### Example

In the following example, returns the string 'QUADRATIC' with all characters changed to uppercase according to the current character set mapping.

```
select ucase('QuadRatic');
       ucase
-----
QUADRATIC
(1 row)
```

### F.53.2.2.14. SUBSTR

#### Description

Return the substring as specified

#### Syntax

```
substr(str text, pos int) RETURNS text
substr(str text, pos int, len int) RETURNS text
```

#### General rules

- The forms without a len argument return a substring from string str starting at position pos. The forms with a len argument return a substring len characters long from string str, starting at position pos.
- It is also possible to use a negative value for pos. In this case, the beginning of the substring is pos characters from the end of the string, rather than the beginning. A negative value may be used for pos in any of the forms of this function. A value of 0 for pos returns an empty string.
- This function is multibyte safe. It returns NULL if any of its arguments are NULL.
- If len is less than 1, the result is the empty string.
- It is also possible for both pos and len to accept numeric type, if the fractional part of a input less than 0.5, round to integer part, otherwise round to floor of input + 0.5 for a positive input, floor of input-0.5 would be applied if input is negative.

#### Example

In the following example, the result is bc

```
select substr('abc',-2,2);
       substr
-----
bc
(1 row)
```

### F.53.2.2.15. SUBSTRING

#### Description

Return the substring as specified

#### Syntax

```
substring(str text, pos int) RETURNS text
```

substring(str text, pos int, len int) RETURNS text

**General rules**

- substring is a synonym for substr

**Example**

In the following example, the result is bc

```
select substring('abc',-2,2);
  substring
-----
      bc
(1 row)
```

**F.53.2.2.16. SUBSTRING\_INDEX****Description**

Return a substring from a string before the specified number of occurrences of the delimiter

**Syntax**

```
substring_index(str varchar, delim varchar, count integer) RETURNS
varchar
```

**General rules**

- Returns the substring from string str before count occurrences of the delimiter delim.
- If count is positive, everything to the left of the final delimiter (counting from the left) is returned.
- If count is negative, everything to the right of the final delimiter (counting from the right) is returned.
- SUBSTRING\_INDEX() performs a case-sensitive match when searching for delim.
- This function is multibyte safe.
- SUBSTRING\_INDEX() returns NULL if any of its arguments are NULL.
- When delim is " return "(same with mysql).

**Example**

```
lightdb@test_m=# SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
  substring_index
-----
  www.mysql
(1 row)

lightdb@test_m=# SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
  substring_index
-----
  mysql.com
```

(1 row)

### F.53.2.3. Date/Time Functions

The following date/time functions are supported:

- DATEDIFF
- DATE\_ADD
- DATE\_FORMAT
- DATE\_SUB
- DAY
- DAYOFWEEK
- FROM\_UNIXTIME
- STR\_TO\_DATE
- SYSDATE
- SEC\_TO\_TIME
- TIME\_TO\_SEC
- TIMEDIFF
- TIMESTAMPDIFF
- TO\_DAYS
- TO\_SECONDS
- UNIX\_TIMESTAMP
- WEEKOFYEAR
- YEAR
- QUARTER
- LAST\_DAY
- CURDATE

#### F.53.2.3.1. DATEDIFF

##### Description

Subtract two dates.

##### Syntax

```
DATEDIFF(expr1 timestamp,expr2 timestamp) RETURN integer  
DATEDIFF(expr1 text,expr2 text) RETURN integer  
DATEDIFF(expr1 timestamptz,expr2 timestamptz) RETURN integer  
DATEDIFF(expr1 timestamptz,expr2 timestamp) RETURN integer  
DATEDIFF(expr1 timestamp,expr2 timestamptz) RETURN integer
```

```
DATEDIFF(expr1 date, expr2 date) RETURN integer
DATEDIFF(expr1 date, expr2 numeric) RETURN integer
DATEDIFF(expr1 numeric, expr2 date) RETURN integer
DATEDIFF(expr1 numeric, expr2 numeric) RETURN integer
```

**General rules**

- *expr1 - expr2* expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.
- Returns NULL if any argument is NULL.
- Parameter can't be time type(mysql can be time type).

**Example**

In the following example, 1 is returned because '2007-12-31' minus '2007-12-30' equals 1

```
SELECT DATEDIFF('2007-12-31 23:59:59', '2007-12-30');
datediff
-----
1
(1 row)
SELECT DATEDIFF(cast('2007-12-31 23:59:59' as
  datetime), cast('2007-12-30' as datetime));
datediff
-----
1
(1 row)
SELECT DATEDIFF(cast('2007-12-31 23:59:59' as
  date), cast('2007-12-30' as date));
datediff
-----
1
(1 row)
```

**F.53.2.3.2. DATE\_ADD****Description**

Date addition.

**Syntax**

```
DATE_ADD(expr1 timestampz, expr2 interval) RETURN date
DATE_ADD(expr1 text, expr2 interval) RETURN date
```

**General rules**

- Returns the date type after adding interval (year / month / day) to the *expr1* date parameter
- The second parameter *expr2* only support interval (year / month / day)

**Example**

In the following example, '2020-01-02' is returned because '20200101' add 1 day

```

select date_add('20200101', interval 1 day);
       date_add
-----
2020-01-02
(1 row)

```

### F.53.2.3.3. DATE\_FORMAT

#### Description

Date format display.

#### Syntax

```

DATE_FORMAT(expr1 timestamp, expr2 text) RETURN text
DATE_FORMAT(expr1 timestamptz, expr2 text) RETURN text
DATE_FORMAT(expr1 text, expr2 text) RETURN text

```

#### General rules

- Return expr1 time parameter, display and output in expr2 format

#### Example

In the following example, '2021/12/01 11,59,59' is returned because expr2is in '%Y/%m/%d %h,%i,%s' format

```

select date_format('20211201 11:59:59', '%Y/%m/%d %h,%i,%s');
       date_format
-----
2021/12/01 11,59,59
(1 row)

```

Table F.83 shows the template patterns available for formatting date\_format values.

**Table F.83. Template Patterns for date\_format Formatting**

Pattern	Description
%a	Abbreviated week name
%b	Abbreviated month name
%c	Month, value
%D	Day of the month with English prefix
%d	Day of month, value (00-31)
%e	Day of month, value (0-31)
%f	Microsecond
%H	Hours (00-23)
%h	Hours (01-12)
%I	Hours (01-12)
%i	Minute, value (00-59)

Pattern	Description
%j	Day of year (001-366)
%k	Hours (0-23)
%l	Hours (1-12)
%M	Month Name
%m	Month, value (00-12)
%P	AM or PM
%r	Time, 12 hours (hh: mm: ss AM or PM)
%S	Seconds (00-59)
%s	Seconds (00-59)
%T	Time, 24 hours (hh: mm: ss)
%W	Week Name
%Y	Year, 4 digits
%y	Year, 2 digits

#### F.53.2.3.4. DATE\_SUB

##### Description

Date subtraction.

##### Syntax

```
DATE_SUB(expr1 timestampz, expr2 interval) RETURN date
DATE_SUB(expr1 text, expr2 interval) RETURN date
```

##### General rules

- Returns the date type after the expr1 date parameter minus the interval (year / month / day)
- The second parameter expr2 only support interval (year / month / day)

##### Example

In the following example, '2019-12-31' is returned because '20200101' minus 1 day

```
select date_sub('20200101', interval 1 day);
   date_sub
-----
2019-12-31
(1 row)
```

#### F.53.2.3.5. DAY

##### Description

Return month date.

##### Syntax

```
DAY(expr1 text) RETURN int2
DAY(expr1 timestamptz) RETURN int4
```

**General rules**

- Returns the date part of a given expr1 date month
- Only month and day parameters are not supported, such as '0101', 0704

**Example**

In the following example, '1' is returned because 2011/12/01's date is 1

```
select day('2011/12/01');
day
-----
    1
(1 row)
```

**F.53.2.3.6. DAYOFWEEK****Description**

Return to the day of the week.

**Syntax**

```
DAYOFWEEK(expr1 text) RETURN int4
DAYOFWEEK(expr1 timestamptz) RETURN int4
```

**General rules**

- Returns the day of the week according to the expr1 date parameter. The return value is 1 ~ 7, and Sunday is 1
- At least include the complete time format, such as 20200202, 200202. Parameters less than 6 bits are not supported

**Example**

In the following example, '4' is returned because 20200101 is Wednesday

```
select dayofweek(20200101);
dayofweek
-----
          4
(1 row)
```

**F.53.2.3.7. FROM\_UNIXTIME****Description**

Return time format according to UNIX timestamp.

**Syntax**

```
FROM_UNIXTIME(expr1 text) RETURN timestamp
FROM_UNIXTIME(expr1 int8) RETURN timestamp
FROM_UNIXTIME(expr1 text, expr2 text) RETURN text
FROM_UNIXTIME(expr1 int8, expr2 text) RETURN text
```

**General rules**

- Return time format according to expr1 parameter UNIX timestamp. The date format can be specified according to the expr2 parameter

**Example**

In the following example, timestamp is returned according to UNIX timestamp 20220910

```
select from_unixtime(20220910);
      from_unixtime
-----
1970-08-23 08:55:10
(1 row)
select from_unixtime(20220910, '%Y/%m/%d %h,%i,%s');
      from_unixtime
-----
1970/08/23 08,55,10
(1 row)
```

Table F.84 shows the template patterns available for formatting from\_unixtime values.

**Table F.84. Template Patterns for from\_unixtime Formatting**

Pattern	Description
%a	Abbreviated week name
%b	Abbreviated month name
%c	Month, value
%D	Day of the month with English prefix
%d	Day of month, value (00-31)
%e	Day of month, value (0-31)
%f	Microsecond
%H	Hours (00-23)
%h	Hours (01-12)
%I	Hours (01-12)
%i	Minute, value (00-59)
%j	Day of year (001-366)
%k	Hours (0-23)
%l	Hours (1-12)
%M	Month Name
%m	Month, value (00-12)
%p	AM or PM
%r	Time, 12 hours (hh: mm: ss AM or PM)

Pattern	Description
%S	Seconds (00-59)
%s	Seconds (00-59)
%T	Time, 24 hours (hh: mm: ss)
%W	Week Name
%Y	Year, 4 digits
%y	Year, 2 digits

### F.53.2.3.8. SEC\_TO\_TIME

#### Description

Converts seconds to 'hh:mm:ss' format.

#### Syntax

```
sec_to_time(p_secs int) RETURNS interval
```

#### General rules

- Returns the seconds argument, converted to hours, minutes, and seconds, as a TIME value.
- The range of the result is constrained to that of the TIME data type. A warning occurs if the argument corresponds to a value outside that range.

#### Example

In the following example, Converts seconds 80580 to 'hh:mm:ss' format 22:23:00.

```
select mysql.sec_to_time(80580);
sec_to_time
-----
22:23:00
(1 row)
```

### F.53.2.3.9. STR\_TO\_DATE

#### Description

Convert string to time value. This is the inverse of the DATE\_FORMAT() function. It takes a string str and a format string format. STR\_TO\_DATE() returns a DATETIME value if the format string contains both date and time parts, or a DATE or TIME value if the string contains only date or time parts. If the date,time, or datetime value extracted from str is illegal, STR\_TO\_DATE() returns error.

#### Syntax

```
STR_TO_DATE(datetime_str text, datetime_format text) RETURN
  datetime
STR_TO_DATE(date_str text, date_format text) RETURN date
STR_TO_DATE(time_str text, time_format text) RETURN time
```

#### General rules

- Convert string str parameter and format format parameter to time value
- If the NO\_ZERO\_DATE SQL mode is enabled, zero dates are disallowed. In that case, STR\_TO\_DATE() returns NULL.

**Example**

In the following example, '2022-09-10 11:13:13' is returned according to timestamp '2022/09/10 11,13,13' and format '%Y/%m/%d %h,%i,%s'. It returns a DATETIME value if the format string contains both date and time parts.

```
select str_to_date('2022/09/10 11,13,13', '%Y/%m/%d %h,%i,%s');
      str_to_date
-----
2022-09-10 11:13:13
(1 row)
```

In the following example, returns a DATE value because of the format string contains only date parts.

```
select str_to_date('2022/09/10', '%Y/%m/%d');
      str_to_date
-----
2022-09-10
(1 row)
```

In the following example, returns a TIME value because of the format string contains only time parts.

```
select str_to_date('09:00:59', '%h:%i:%s');
      str_to_date
-----
09:00:59
(1 row)
```

If the NO\_ZERO\_DATE SQL mode is enabled, zero dates are disallowed. In that case, STR\_TO\_DATE() return NULL:

```
set lightdb_sql_mode = 'no_zero_date';
select str_to_date('2022/09/0', '%Y/%m/%d');
      str_to_date
-----

(1 row)
```

Table F.85 shows the template patterns available for formatting str\_to\_date values.

**Table F.85. Template Patterns for str\_to\_date Formatting**

Pattern	Description
%a	Abbreviated week name
%b	Abbreviated month name
%c	Month, value

Pattern	Description
%D	Day of the month with English prefix
%d	Day of month, value (00-31)
%e	Day of month, value (0-31)
%f	Microsecond
%H	Hours (00-23)
%h	Hours (01-12)
%I	Hours (01-12)
%i	Minute, value (00-59)
%j	Day of year (001-366)
%k	Hours (0-23)
%l	Hours (1-12)
%M	Month Name
%m	Month, value (00-12)
%P	AM or PM
%r	Time, 12 hours (hh: mm: ss AM or PM)
%S	Seconds (00-59)
%s	Seconds (00-59)
%T	Time, 24 hours (hh: mm: ss)
%W	Week Name
%Y	Year, 4 digits
%y	Year, 2 digits

### F.53.2.3.10. SYSDATE

#### Description

Return the time at which the function executes.

#### Syntax

```
sysdate() RETURNS timestamp(0)
```

#### General rules

- Returns the time at which it executes, it is nondeterministic.
- The return value affected by timezone setting.
- Available since version 23.2

#### Examples as below:

```
select sysdate;
        sysdate
-----
2023-05-06 16:06:59
(1 row)
```

### F.53.2.3.11. TIME\_TO\_SEC

**Description**

Return the argument converted to seconds.

**Syntax**

```
time_to_sec(p_time time) RETURNS int
```

**General rules**

- Returns the time argument, converted to seconds.

**Example**

In the following example, returns the time argument '22:23:00' converted to seconds 80580.

```
select time_to_sec('22:23:00');
time_to_sec
-----
          80580
(1 row)
```

### F.53.2.3.12. TIMEDIFF

**Description**

Subtract time.

**Syntax**

```
timediff(p_date1 timestamptz, p_date2 timestamptz) RETURNS interval
```

**General rules**

- TIMEDIFF() returns expr1 \_ expr2 expressed as a time value. expr1 and expr2 are time or date-and-time expressions, but both must be of the same type.
- The result returned by TIMEDIFF() is limited to the range allowed for TIME values. Alternatively, you can use either of the functions TIMESTAMPDIFF() and UNIX\_TIMESTAMP(), both of which return integers.

**Example**

In the following example, returns '2000-01-01 00:00:00' \_ '2000-01-01 00:00:00.000001' expressed as a time value.

```
select mysql.timediff('2000-01-01 00:00:00', '2000-01-01
00:00:00.000001');
timediff
-----
-00:00:00.000001
(1 row)
```

### F.53.2.3.13. TIMESTAMPDIFF

#### Description

Subtract an interval from a datetime expression.

#### Syntax

```
timestampdiff( p_unit text, p_ts1 text, p_ts2 text) RETURNS
  bigint
timestampdiff( p_unit text, p_ts1 text, p_ts2 timestampz)
  RETURNS bigint
timestampdiff( p_unit text, p_ts1 timestampz, p_ts2 text)
  RETURNS bigint
timestampdiff( p_unit text, p_ts1 timestampz, p_ts2 timestampz)
  RETURNS bigint
```

#### General rules

- Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions.
- One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary.
- The unit for the result (an integer) is given by the unit argument. The unit parameters support MICROSECOND, SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER and YEAR, with or without quotes.

#### Example

In the following example, Returns '1911-11-11 11:23:45.123456' - '2021-12-12 12:12:12.654321'::timestamp, the result (an integer) is given by MICROSECOND.

```
select timestampdiff ('MICROSECOND', '1911-11-11
  11:23:45.123456'::timestamp, '2021-12-12
  12:12:12.654321'::timestamp);
  timestampdiff
-----
3474060507530865
(1 row)
```

```
select timestampdiff (MICROSECOND, '1911-11-11
  11:23:45.123456'::timestamp, '2021-12-12
  12:12:12.654321'::timestamp);
  timestampdiff
-----
3474060507530865
(1 row)
```

### F.53.2.3.14. TO\_DAYS

#### Description

Return the date argument converted to days.

#### Syntax

```
to_days(p_date timestamp) RETURNS bigint
to_days(p_date timestampz) RETURNS bigint
to_days( p_date text) RETURNS bigint
to_days( p_date text, p_format text) RETURNS bigint
to_days(p_date bigint) RETURNS bigint
```

**General rules**

- Given a date `date`, returns a day number (the number of days since year 0).
- `TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable.

**Example**

In the following example, return the date argument '1111-11-11' converted to days 406098.

```
select to_days('1111-11-11');
to_days
-----
    406098
(1 row)
```

**F.53.2.3.15. TO\_SECONDS****Description**

Return the date or datetime argument converted to seconds since Year 0.

**Syntax**

```
to_seconds(p_date timestamp) RETURNS bigint
to_seconds(p_date timestampz) RETURNS bigint
```

**General rules**

- Given a date or datetime `expr`, returns the number of seconds since the year 0. If `expr` is not a valid date or datetime value, returns `NULL`.
- Like `TO_DAYS()`, `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable.

**Example**

In the following example, Return the date or datetime argument '2009-11-29' converted to seconds 63426672000 since Year 0.

```
select to_seconds('2009-11-29'::timestamp);
to_seconds
-----
```

```
63426672000
(1 row)
```

### F.53.2.3.16. UNIX\_TIMESTAMP

#### Description

Return UNIX timestamp according to time format.

#### Syntax

```
UNIX_TIMESTAMP() RETURN int8
UNIX_TIMESTAMP(expr1 timestamptz) RETURN int8
UNIX_TIMESTAMP(expr1 text) RETURN int8
```

#### General rules

- Returns the UNIX timestamp according to the expr1 parameter time format. If there is no parameter, returns the current UNIX timestamp
- Expr1 parameter contains at least the complete log format, such as 20200101

#### Example

In the following example, Return the unix timestamp '1577808000' corresponding parameter 20200101.

```
select unix_timestamp(20200101);
   unix_timestamp
-----
          1577808000
(1 row)
select unix_timestamp();
   unix_timestamp
-----
          1663051334
(1 row)
```

### F.53.2.3.17. WEEKOFYEAR

#### Description

According to the time, return to the week within a year.

#### Syntax

```
WEEKOFYEAR(expr1 timestamptz) RETURN int4
WEEKOFYEAR(expr1 text) RETURN int4
```

#### General rules

- According to the time expr1 parameter, return to the week within a year
- At least include the complete time format, such as 20200202, 200202. Parameters less than 6 bits are not supported

**Example**

In the following example, '36' is returned because '20220910' is the 36th week of the year

```
select weekofyear('20220910');
   weekofyear
-----
                36
(1 row)
```

**F.53.2.3.18. YEAR****Description**

Returns the year of the date.

**Syntax**

```
YEAR(expr1 timestampz) RETURN int4
YEAR(expr1 text) RETURN int4
```

**General rules**

- Returns the year according to the expr1 parameter date
- It supports complete month, day and month time parameters, such as '20200101' and '200101'. It does not support only including month and day parameters, such as '0101' and '0704'

**Example**

In the following example, '2020' is returned because the year of '20200101' is 2020

```
select year(20200101);
   year
-----
    2020
(1 row)
select year('200101');
   year
-----
    2020
(1 row)
```

**F.53.2.3.19. QUARTER****Description**

Returns the quarter of the year for date, in the range 1 to 4.

**Syntax**

```
QUARTER(timestamp) RETURN int4
```

**General rules**

- NULL if date is NULL.
- It only supports the timestamp type, and any type that can be implicitly converted to a timestamp type now (like date type).

**Example**

In the following example, '4' is returned because the quarter of '20201001' is 4

```
select quarter(cast('20201001'as date));
quarter
-----
         4
(1 row)

select quarter(cast('20201001'as datetime));
quarter
-----
         4
(1 row)

select quarter('20201001');
quarter
-----
         4
(1 row)
```

**F.53.2.3.20. LAST\_DAY****Description**

Returns the corresponding value for the last day of the month.

**Syntax**

```
LAST_DAY(date) RETURN date
LAST_DAY(text) RETURN date
```

**General rules**

- Returns NULL if the argument is NULL.
- Error if the argument is invalid.
- It only supports date and text type (also includes any data type that can be implicitly converted to either type) now.

**Example**

In the following example, last day of the month is returned if parameter is valid:

```
lightdb@test_m=# SELECT LAST_DAY('2003-02-05');
last_day
```

```
-----
2003-02-28
(1 row)

lightdb@test_m=# SELECT LAST_DAY('2004-02-05');
      last_day
-----
2004-02-29
(1 row)

lightdb@test_m=# SELECT LAST_DAY('2004-01-01 01:01:01');
      last_day
-----
2004-01-31
(1 row)

lightdb@test_m=# SELECT LAST_DAY('2003-03-32');
ERROR:  date/time field value out of range: "2003-03-32"
HINT:   Perhaps you need a different "datestyle" setting.
CONTEXT: SQL function "last_day" statement 1
lightdb@test_m=#
```

### F.53.2.3.21. CURDATE

#### Description

Returns the current date as a value in 'YYYY-MM-DD' format.

#### Syntax

```
CURDATE() RETURN date
```

#### General rules

- Cannot return YYYYMMDD format like mysql yet, therefore, multiplication and division are not supported, addition and subtraction results are different from mysqls. Mysql will Returns the current date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in string or numeric context.

#### Example

```
lightdb@test_m=# select curdate();
      curdate
-----
2023-12-06
(1 row)

lightdb@test_m=# select curdate()+1;
      ?column?
-----
2023-12-07
(1 row)

lightdb@test_m=# select curdate()/2;
ERROR:  operator does not exist: date / integer
```

```
LINE 1: select curdate()/2;
          ^
```

HINT: No operator matches the given name and argument types. You might need to add explicit type casts.

```
lightdb@test_m=# select curdate()*2;
```

ERROR: operator does not exist: date \* integer

```
LINE 1: select curdate()*2;
          ^
```

HINT: No operator matches the given name and argument types. You might need to add explicit type casts.

```
lightdb@test_m=# select curdate()-2;
?column?
```

-----

```
2023-12-04
```

```
(1 row)
```

## F.53.2.4. JSON Functions

The following json functions are supported:

- JSON\_ARRAY
- JSON\_OBJECT
- JSON\_EXTRACT
- JSON\_CONTAINS
- JSON\_CONTAINS\_PATH
- JSON\_PRETTY
- JSON\_REMOVE
- JSON\_INSERT
- JSON\_REPLACE
- JSON\_SET

### F.53.2.4.1. JSON\_ARRAY

#### Description

Evaluates a (possibly empty) list of values and returns a JSON array containing those values.

#### Syntax

```
JSON_ARRAY( VARIADIC "any" ) RETURNS jsonb
```

#### General rules

- Returns a JSON array, the data type is jsonb.

#### Example

```
SELECT JSON_ARRAY(1, 'abc', NULL, TRUE, NOW());
```

json\_array

```
-----  
[1, "abc", null, true, "2023-05-31T19:44:44.881055+08:00"]  
(1 row)
```

### F.53.2.4.2. JSON\_OBJECT

#### Description

Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs.

#### Syntax

```
JSON_OBJECT( VARIADIC "any" ) RETURNS jsonb
```

#### General rules

- Returns a JSON object, the data type is jsonb.
- An error occurs if any key name is NULL or the number of arguments is odd.

#### Example

```
SELECT JSON_OBJECT('id', 87, 'name', 'carrot');  
          json_object  
-----  
{"id": 87, "name": "carrot"}  
(1 row)  
  
SELECT JSON_OBJECT('id', 87, 'name', 'carrot', 'id', 99);  
          json_object  
-----  
{"id": 99, "name": "carrot"}  
(1 row)
```

### F.53.2.4.3. JSON\_EXTRACT

#### Description

Returns data from a JSON document, selected from the parts of the document matched by the path arguments.

#### Syntax

```
JSON_EXTRACT(json_doc jsonb, path jsonpath) RETURNS jsonb
```

#### General rules

- The return value consists of all values matched by the path arguments, the data type is jsonb. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.
- Returns NULL if any argument is NULL or no paths locate a value in the document.

- An error occurs if the `json_doc` argument is not a valid JSON document or any path argument is not a valid path expression.

**Example**

```
SELECT JSON_EXTRACT('{"k1":11,"k2":22,"k2 2":33}','$.k1');
      json_extract
```

```
-----
      11
(1 row)
```

```
SELECT JSON_EXTRACT('{"k1":11,"k2":22,"k2 2":33}','$.k2 2');
      json_extract
```

```
-----
      33
(1 row)
```

```
SELECT JSON_EXTRACT('{"a":{"c":20, "d":{"b":{"b":30, "c":40}, "e":
{"b":50}}}, "c":{"b":60, "c":70}, "b":80}','$.a.c');
      json_extract
```

```
-----
      20
(1 row)
```

```
SELECT JSON_EXTRACT('[10,"str", null, true]','$[1]');
      json_extract
```

```
-----
      "str"
(1 row)
```

```
SELECT JSON_EXTRACT('[10,"str", null, true]','$[last]');
      json_extract
```

```
-----
      true
(1 row)
```

```
SELECT JSON_EXTRACT('[10,"str", null, true]','$[last-2]');
      json_extract
```

```
-----
      "str"
(1 row)
```

In the following example, multiple values matched, they are autowrapped as an array.

```
SELECT JSON_EXTRACT('[10,"str", null, true]','$[1 to 3]');
      json_extract
```

```
-----
["str", null, true]
(1 row)
```

```
SELECT JSON_EXTRACT('[10,"str", null, true]','$[*]');
      json_extract
```

```
-----
[10, "str", null, true]
(1 row)
```

```
SELECT JSON_EXTRACT('[10]', '$[*]');
       json_extract
-----
      [10]
(1 row)
```

```
SELECT JSON_EXTRACT('{"k1":1,"k2":"22","k2 2":[3,33]}', '$.*');
       json_extract
-----
      [1, "22", [3, 33]]
(1 row)
```

#### F.53.2.4.4. JSON\_CONTAINS

##### Description

Indicates by returning true or false whether a given candidate JSON document is contained within a target JSON document.

##### Syntax

```
JSON_CONTAINS(json_doc jsonb, json_val jsonb, path jsonpath)
RETURNS bool
```

##### General rules

- Returns NULL if any argument is NULL, or if the path argument does not identify a section of the target document.
- An error occurs if target or candidate is not a valid JSON document.
- To check only whether any data exists at the path, use JSON\_CONTAINS\_PATH() instead.

##### Example

```
SELECT JSON_CONTAINS('{"a": 111, "b": 222, "c": {"d": 4444}}',
       '111', '$.a');
       json_contains
-----
          t
(1 row)
```

```
SELECT JSON_CONTAINS('{"a": "111", "b": 222, "c": {"d": 4444}}',
       '111', '$.a');
       json_contains
-----
          f
(1 row)
```

```
SELECT JSON_CONTAINS('{"a": "111", "b": 222, "c": {"d": 4444}}', '"
111"', '$.a');
       json_contains
-----
          f
(1 row)
```

```

SELECT JSON_CONTAINS('{ "a": 111, "b": 222, "c": { "d": 4444 } }',
  '{"d" : 4444 }', '$.c');
  json_contains
-----
t
(1 row)

```

### F.53.2.4.5. JSON\_CONTAINS\_PATH

#### Description

Returns true or false to indicate whether a JSON document contains data at a given path or paths.

#### Syntax

```

JSON_CONTAINS_PATH(json_doc jsonb, one_or_all text, variadic
  jsonpath[]) RETURNS bool

```

#### General rules

- The return value is false if no specified path exists within the document. Otherwise, the return value depends on the `one_or_all` argument:
  - 'one' : true if at least one path exists within the document, false otherwise.
  - 'all' : true if all paths exist within the document, false otherwise.
- An error occurs if the `json_doc` argument is not a valid JSON document, any path argument is not a valid path expression, or `one_or_all` is not 'one' or 'all'.
- To check for a specific value at a path, use `JSON_CONTAINS()` instead.

#### Example

```

SELECT JSON_CONTAINS_PATH('{ "a": 111, "b": 222, "c": { "d": 4444 } }',
  'one', '$.a', '$.z');
  json_contains_path
-----
t
(1 row)

```

```

SELECT JSON_CONTAINS_PATH('{ "a": 111, "b": 222, "c": { "d": 4444 } }',
  'one', '$.d');
  json_contains_path
-----
f
(1 row)

```

```

SELECT JSON_CONTAINS_PATH('{ "a": 111, "b": 222, "c": { "d": 4444 } }',
  'all', '$a', '$.b', '$.c');
  json_contains_path
-----
t
(1 row)

```

```

SELECT JSON_CONTAINS_PATH('{ "a": 111, "b": 222, "c": { "d": 4444} }',
  'all', '$a', '$.b', '$.d');
  json_contains_path
-----
f
(1 row)

```

### F.53.2.4.6. JSON\_PRETTY

#### Description

Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems.

#### Syntax

```
JSON_PRETTY(json_doc jsonb) RETURNS text
```

#### General rules

- The data type of return value is `text`.
- The value supplied must be a JSON value or a valid string representation of a JSON value. Extraneous whitespaces and newlines present in this value have no effect on the output.
- For a NULL value, the function returns NULL. If the value is not a JSON document, or if it cannot be parsed as one, the function fails with an error.

#### Example

```

SELECT JSON_PRETTY('{ "a": { "b": { "z": 1 } }, "c": [ 5, { "z": 2 } ], "z": 3 },
  "z": 4 }');
  json_pretty
-----
{
  "a": {
    "b": {
      "z": 1
    },
    "c": [
      5,
      {
        "z": 2
      }
    ],
    "z": 3
  },
  "z": 4
}
(1 row)

```

### F.53.2.4.7. JSON\_REMOVE

#### Description

Removes data from a JSON document and returns the result.

## Syntax

JSON\_REMOVE(jsonb, jsonpath) RETURNS jsonb

## General rules

- Removes data from a JSON document and returns the result. Returns NULL if any argument is NULL.
- An error occurs if the jsonb argument is not a valid JSON document or any path argument is not a valid path expression or is \$ or contains a \* or \*\* wildcard.
- It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.

## Example

```
SELECT JSON_REMOVE('{ "a": 1, "b": [1,2,3], "c": {"d": 4} }',  
 '$.c.d');
```

```
      json_remove
```

```
-----  
{ "a": 1, "b": [1, 2, 3], "c": {} }  
(1 row)
```

```
SELECT JSON_REMOVE('{ "a": 1, "b": [1,2,3], "c": {"d": 4} }',  
 '$.b[last]');
```

```
      json_remove
```

```
-----  
{ "a": 1, "b": [1, 2], "c": {"d": 4} }  
(1 row)
```

```
SELECT JSON_REMOVE('{ "a": 1, "b": [1,2,3], "c": {"d": 4} }',  
 '$.c.z');
```

```
      json_remove
```

```
-----  
{ "a": 1, "b": [1, 2, 3], "c": {"d": 4} }  
(1 row)
```

Different from MySQL, when accessing a JSON object through period ., if the object name is not enclosed in double quotes and it is a valid ECMAScript identifier name with some special characters (like \$), LightDB will prompt an error.

```
SELECT JSON_REMOVE('{ "a": 1, "b": [1,2,3], "c": {"d": 4} }', '$.  
$z');
```

## F.53.2.4.8. JSON\_INSERT

### Description

Inserts data into a JSON document and returns the result.

### Syntax

```
JSON_INSERT(jsonb, jsonpath, anyelement) RETURNS jsonb
JSON_INSERT(jsonb, jsonpath, text) RETURNS jsonb
```

**General rules**

- Inserts data into a JSON document and returns the result. Returns NULL if any argument is NULL.
- An error occurs if the jsonb argument is not a valid JSON document or any path argument is not a valid path expression or contains a \* or \*\* wildcard.
- A path-value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path-value pair for a nonexisting path in the document adds the value to the document.

**Example**

```
SELECT JSON_INSERT('{ "a": 1, "b": [2, 3]}', '$.a', 10);
      json_insert
-----
{"a": 1, "b": [2, 3]}
(1 row)

SELECT JSON_INSERT('{ "a": 1, "b": [2, 3]}', '$.c', 200);
      json_insert
-----
{"a": 1, "b": [2, 3], "c": 200}
(1 row)
```

### F.53.2.4.9. JSON\_REPLACE

**Description**

Replaces existing values in a JSON document and returns the result.

**Syntax**

```
JSON_REPLACE(jsonb, jsonpath, anyelement) RETURNS jsonb
JSON_REPLACE(jsonb, jsonpath, text) RETURNS jsonb
```

**General rules**

- Replaces existing values in a JSON document and returns the result. Returns NULL if any argument is NULL.
- An error occurs if the jsonb argument is not a valid JSON document or any path argument is not a valid path expression or contains a \* or \*\* wildcard.
- A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document is ignored and has no effect.

**Example**

```
SELECT JSON_REPLACE('{ "a": 1, "b": [2, 3]}', '$.a', 10);
      json_replace
-----
```

```
{ "a": 10, "b": [2, 3] }
(1 row)
```

```
SELECT JSON_REPLACE('{ "a": 1, "b": [2, 3] }', '$.c', 'null');
       json_replace
```

```
-----
{ "a": 1, "b": [2, 3] }
(1 row)
```

```
SELECT JSON_REPLACE('100', '$', '{ "a": 1, "b": [2, 3] }'::jsonb);
       json_replace
```

```
-----
{ "a": 1, "b": [2, 3] }
(1 row)
```

Different from MySQL, when accessing a JSON object through period ., if the object name is not enclosed in double quotes and it is an illegal ECMAScript identifier name, LightDB will not prompt an error but return the original value.

```
SELECT JSON_REPLACE('{ "a": 1, "b": [2, 3] }', '$.b.2z', 4);
       json_replace
```

```
-----
{ "a": 1, "b": [2, 3] }
(1 row)
```

#### F.53.2.4.10. JSON\_SET

##### Description

Inserts or updates data in a JSON document and returns the result.

##### Syntax

```
JSON_SET(jsonb, jsonpath, anyelement) RETURNS jsonb
JSON_SET(jsonb, jsonpath, text) RETURNS jsonb
```

##### General rules

- Inserts or updates data in a JSON document and returns the result. Returns NULL if json\_doc or path is NULL.
- An error occurs if the jsonb argument is not a valid JSON document or any path argument is not a valid path expression or contains a \* or \*\* wildcard.
- A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document adds the value to the document.

##### Example

```
SELECT JSON_SET('{ "a": 1, "b": [2, 3] }', '$.a', 10);
       json_set
```

```
-----
{ "a": 10, "b": [2, 3] }
```

```
(1 row)

SELECT JSON_SET('{ "a": 1, "b": [2, 3]}', '$.c', '[true, false]');
           json_set
-----
{"a": 1, "b": [2, 3], "c": "[true, false]"}
(1 row)

SELECT JSON_SET('{ "a": 1, "b": [2, 3]}', '$.b.z', 4);
           json_set
-----
{"a": 1, "b": [2, 3]}
(1 row)
```

## F.53.2.5. Conditional Expressions

The following functions for making comparisons are supported:

- IF

### F.53.2.5.1. IF

#### Description

If expr1 is TRUE, IF() returns expr2. Otherwise, it returns expr3.

#### Syntax

```
IF(expr1, expr2, expr3)
```

#### General rules

- If only one of expr2 or expr3 is explicitly NULL, the result type of the IF() function is "text".
- If one of expr2 and expr3 is a string, the result type of the IF() function is "text", otherwise it is "numeric".
- The following data types can be used in expr2 and expr3:
  - CHAR
  - VARCHAR
  - TEXT
  - INTEGER
  - BIGINT
  - SMALLINT
  - NUMERIC
  - REAL
  - DOUBLE PRECISION
  - BOOLEAN

- TIMESTAMPTZ

**Example**

In the following example, 3 is returned because the value of  $1 > 2$  is false.

```
SELECT IF(1>2,2,3);
   if
----
   3
(1 row)
```

## F.53.2.6. Aggregate Functions

The following aggregation functions are supported:

- ANY\_VALUE
- GROUP\_CONCAT

### F.53.2.6.1. ANY\_VALUE

**Description**

For compatibility with MySQL mode non ONLY\_FULL\_GROUP\_BY syntax behavior of group by in by mode.

**Syntax**

```
ANY_VALUE(anyelement)
```

**General rules**

- This function is useful for in MySQL compatible GROUP BY queries when the ONLY\_FULL\_GROUP\_BY SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine, Default ANY\_VALUE will return the first line causing ambiguity. The function return value and type are the same as the return value and type of its argument.

Note that this behavior is only a nonstandard syntax compatible with MySQL. It is used to ensure that the execution in LightDB will not report errors, but the results cannot be guaranteed to be completely consistent with MySQL. It is not recommended to use this feature. Please use the standard syntax format.

**Example**

In the following example, if id is a nonindexed column, the following query fails:

```
select col1, co2, max(co3) from t1 group by id;
ERROR: column "t1.col1" must appear in the GROUP BY clause or be
       used in an aggregate function
LINE 1: select col1, co2, max(co3) from t1 group by id;
              ^
```

Use ANY\_VALUE() to refer to col1 and col2:

```
select any_value(col1) as col1, any_value(col2) as col2, max(col3) from
t1 group by id;
col1 | col2 | max
-----+-----+-----
  6 |    9 |   30
  4 |    5 |    5
  3 |    3 |    4
  2 |    3 |    4
(4 rows)
```

### F.53.2.6.2. GROUP\_CONCAT

#### Description

Returns a concatenated, delimited list of string values.

#### Syntax

```
GROUP_CONCAT( [DISTINCT] column_name1 [ORDER BY {unsigned_integer
| column_name2 | expr} [ASC | DESC] [SEPARATOR delimiter TEXT])
returns TEXT
```

#### General rules

- This function returns a string result with the concatenated non-NULL values from a group.
- It returns NULL if there are no non-NULL values.
- To sort values in the result, use the ORDER BY clause. To sort in reverse order, add the DESC (descending) keyword to the name of the column you are sorting by in the ORDER BY clause. The default is ascending order; this may be specified explicitly using the ASC keyword.
- To eliminate duplicate values, use the DISTINCT clause.
- The default separator between values in a group is comma (.). To specify a separator explicitly, use SEPARATOR followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify SEPARATOR "".

#### Example

In the following example, the result with values of column col1 in table t delimited by ':' is returned.

```
select GROUP_CONCAT(col1 separator ':') from (values('BBBB',1),
('AAAA',1),('CCCC',2)) as t(col1 ,col2) group by col2;
group_concat
-----
BBBB:AAAA
CCCC
(2 rows)
```

### F.53.2.7. System Information Functions and Operators

The following System Information functions are supported:

- DATABASE

### F.53.2.7.1. DATABASE

#### Description

Synonym for `current_schema()`. The concept of schema is similar to that of database in MySQL. You can specify the current schema by setting the `search_path`.

#### Syntax

`DATABASE()` returns TEXT

#### General rules

- Returns the name of the schema that is first in the search path (or a null value if the search path is empty).
- Like mysql, This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

#### Example

In the following example, current schema is `lightdb`.

```
select database();
  database
-----
  lightdb
(1 row)
```

## F.53.2.8. Miscellaneous Functions

The following Miscellaneous Functions are supported:

- BIN\_TO\_UUID
- COMPRESS
- UNCOMPRESS
- UUID
- UUID\_TO\_BIN

### F.53.2.8.1. BIN\_TO\_UUID

#### Description

Convert binary UUID to string.

#### Syntax

`bin_to_uuid(p_uuid bytea, swap_flag int4 default 0)` RETURNS uuid

#### General rules

- `BIN_TO_UUID()` is the inverse of `UUID_TO_BIN()`. It converts a binary UUID to a string UUID and returns the result. The binary value should be a UUID as a `VARBINARY(16)` value.
- The return value is a utf8 string of five hexadecimal numbers separated by dashes. (For details about this format, see the `UUID()` function description.) If the `UUID` argument is `NULL`, the return value is `NULL`. If any argument is invalid, an error occurs.

**Example**

In the following example, Convert binary UUID '\x0768a47dd355372b4926ee668b6cb443' to string '0768a47d-d355-372b-4926-ee668b6cb443'.

```
select bin_to_uuid('\x0768a47dd355372b4926ee668b6cb443');
           bin_to_uuid
-----
0768a47d-d355-372b-4926-ee668b6cb443
(1 row)
```

**F.53.2.8.2. COMPRESS**

**Description**

Compress string and return binary data.

**Syntax**

```
COMPRESS(expr1 text) RETURN bytea
```

**General rules**

- Compress string `expr1` parameter and return binary data. The corresponding decompression function is `UNCOMPRESS`

**Example**

In the following example, compress 'abc123' into binary data '\x06000000616263313233'.

```
select compress('abc123');
           compress
-----
\x06000000616263313233
(1 row)
```

**F.53.2.8.3. UNCOMPRESS**

**Description**

Decompress the binary data compressed by `compress()` and restore the original string.

**Syntax**

```
UNCOMPRESS(expr1 bytea) RETURN text
```

**General rules**

- Decompress the binary data expr1 parameter compressed by compress() and restore the original string

**Example**

In the following example, decompress binary data '\x06000000616263313233' into bCompress 'abc123'

```
select uncompress(compress('abc123'));
       uncompress
-----
       abc123
(1 row)
```

**F.53.2.8.4. UUID****Description**

returns a randomly generated UUID, as a string of 36 characters.

**Syntax**

```
uuid() RETURNS text
```

**General rules**

- UUID() returns a value that conforms to UUID version 4 as described in RFC 4122. The value is a 128-bit number represented as a utf8 string of five hexadecimal numbers in aaaaaaa-bbbccc-cccc-eeeeeeee format.

**Example**

In the following example, generate random UUID.

```
select uuid();
              uuid
-----
f31f29e5-481f-4666-aa74-8cee3aa44545
(1 row)
```

**F.53.2.8.5. UUID\_TO\_BIN****Description**

Convert string UUID to binary.

**Syntax**

```
uuid_to_bin(p_uuid uuid, swap_flag int4 default 0) RETURNS bytea
```

**General rules**

- Converts a string UUID to a binary UUID and returns the result. (The IS\_UUID() function description lists the permitted string UUID formats.)
- The return binary UUID is a VARBINARY(16) value. If the UUID argument is NULL, the return value is NULL. If any argument is invalid, an error occurs.

**Example**

In the following example, Convert string UUID '0768a47d-d355-372b-4926-ee668b6cb443' to binary '\x0768a47dd355372b4926ee668b6cb443'.

```
select uuid_to_bin('0768a47d-d355-372b-4926-
ee668b6cb443'::uuid)::text;
      uuid_to_bin
-----
\x0768a47dd355372b4926ee668b6cb443
(1 row)
```

## F.53.2.9. Operators

The following Operators are supported:

- IFNULL
- ISNULL

### F.53.2.9.1. IFNULL

**Description**

The corresponding value is returned according to whether the parameter is empty.

**Syntax**

```
IFNULL(expr1 anycompatible, expr2 anycompatible) RETURNS
  anycompatible
IFNULL(expr1 text, expr2 text) RETURNS text
```

**General rules**

- Judge whether the first parameter is null. If it is null, the value of the second parameter will be returned. If it is not null, the value of the first parameter will be returned
- The two input parameters must belong to the same category, and the `typcategory` field of `pg_type` can be determined

**Example**

In the following example, when the first parameter is null, the second parameter 15 is returned; otherwise, the first parameter 1 is returned

```
select ifnull(1, 15);
  ifnull
-----
      1
(1 row)
```

```
select ifnull(null, 15);
   ifnull
-----
        15
(1 row)
```

### F.53.2.9.2. ISNULL

#### Description

Test whether the argument is NULL

#### Syntax

```
isnull(text) RETURNS bool
isnull(numeric) RETURNS bool
isnull(timestampz) RETURNS bool
```

#### General rules

- If expr is NULL, ISNULL() returns true, otherwise it returns false.

#### Example

In the following example, expr is not NULL, ISNULL() returns false.

```
select isnull(0)::text;
   isnull
-----
   false
(1 row)
```

## F.53.2.10. Arithmetic Operators

The following arithmetic operator are supported:

- /

### F.53.2.10.1. /

#### Description

Division operator. Division by zero produces a NULL result, reported a warning log.

#### Example

Division operator examples. Division by zero produces a NULL result, reported a warning log.

```
select 2 / 4;
   ?column?
-----
  0.50000000000000000000
(1 row)
```

```
select 1.0 / 2;
?column?
-----
0.50000000000000000000000000000000
(1 row)

select 2 / 0;
WARNING: division by zero
?column?
-----

(1 row)
```

## F.53.2.11. Compare Operators

The following compare operators are supported:

- =
- !=

### F.53.2.11.1. =

#### Description

Equal operator, support for varchar with bool or text. Got true for equality and false for non-equality.

#### Example

```
select '1'::varchar = true;
?column?
-----
t
(1 row)

select '1'::varchar = '1'::text;
?column?
-----
t
(1 row)

create table a(b varchar(5), c int);
insert into a values(true, 1);
insert into a values('true', 2);

select * from a;
 b | c
---+---
 1 | 1
true | 2
(2 rows)

select * from a where b = true;
 b | c
---+---
 1 | 1
(1 row)
```

```
select * from a where b = 'true';
  b   | c
-----+-----
 true | 2
(1 row)
```

### F.53.2.11.2. !=

#### Description

Non-equal operator, support for varchar with bool or text. Got true for non-equality and false for equality.

#### Example

```
select '1' != true;
?column?
-----
  f
(1 row)
```

```
select '1'::varchar != '1'::text;
?column?
-----
  f
(1 row)
```

```
create table a(b varchar(5), c int);
insert into a values(true, 1);
insert into a values('true', 2);
```

```
select * from a;
  b   | c
-----+-----
  1   | 1
 true | 2
(2 rows)
```

```
select * from a where b != true;
  b   | c
-----+-----
 true | 2
(1 row)
```

```
select * from a where b != 'true';
  b | c
---+---
  1 | 1
(1 row)
```

### F.53.2.12. Convert type

#### F.53.2.12.1. Convert bool type to varchar

##### Description

Previously, bool type would transform to varchar kept invariant as aspect, like true to 'true' or false to 'false'. Myfice changes the rules above, transform bool type true to string '1' and false to string '0' for compatible with mysql.

### Example

```
create table tb (a varchar(5), b int);
insert into tb values('true', 2);           -- insert text 'true' as
expected
insert into tb values(true, 1);           -- insert true of bool
type, expected to insert text '1' instead
insert into tb values(1, 3);             -- insert numeric 1,
expected to insert text '1' instead
insert into tb values('1', 4);          -- insert text '1' as
expected
insert into tb values(false, 5);         -- insert false of bool
type, expected to insert text '0'
insert into tb values('false', 6);      -- insert text 'false' as
expected
insert into tb values(0, 7);             -- insert numeric 0,
expected to insert text '0' instead
insert into tb values('0', 8);          -- insert text '0' as
expected
select * from tb;
a  | b
-----+-----
true | 2
1   | 1
1   | 3
1   | 4
0   | 5
false | 6
0   | 7
0   | 8
(8 rows)
```

### F.53.2.12.2. cast(expr as unsigned)

#### Description

transform expr to unsigned bigint value.

#### General rules

- Return type is numeric type. It is different from mysql, mysql is unsigned bigint type.
- Expr of Date/Time types is not supported to cast yet. See examples for details.
- Floating-point number in character types is not truncated when cast like mysql#'1.9' truncate to 1#. See examples for details.
- Negative floating-point constant is not truncated when cast like mysql8.0, but mysql5.7 truncate it (floating-point number in col is not truncated). See examples for details.
- Negative constant is truncated to 9223372036854775808 when overflowed like mysql8.0(mysql5.7 is 0). See examples for details.
- Support casting strings in scientific notation format to unsigned, like '2e2' to 200(it is different from mysql, mysql is 2 after cast). See examples for details.

**Example**

```
lightdb@test_m=# select cast(123 as unsigned) as unsigned;
      unsigned
-----
          123
(1 row)

lightdb@test_m=# select cast(-123 as unsigned) as unsigned;
      unsigned
-----
18446744073709551493
(1 row)

lightdb@test_m=# select cast(18446744073709551615 as unsigned) as
      unsigned;
-----
18446744073709551615
(1 row)

lightdb@test_m=# select cast(18446744073709551616 as unsigned) as
      unsigned;
-----
18446744073709551615
(1 row)

lightdb@test_m=# select cast(18446744073709551616 as unsigned) as
      unsigned;
WARNING: unsigned bigint out of range, Truncated
      unsigned
-----
18446744073709551615
(1 row)

lightdb@test_m=# select cast(-9223372036854775808 as unsigned) as
      unsigned;
-----
9223372036854775808
(1 row)

-- mysql5.7# 0 #mysql8.0: 9223372036854775808
lightdb@test_m=# select cast(-9223372036854775809 as unsigned) as
      unsigned;
WARNING: unsigned bigint out of range, Truncated
      unsigned
-----
9223372036854775808
(1 row)

lightdb@test_m=# select cast(1.4 as unsigned) as unsigned;
      unsigned
-----
          1
(1 row)

lightdb@test_m=# select cast(1.5 as unsigned) as unsigned;
      unsigned
-----
          2
(1 row)
```

```
lightdb@test_m=# select cast(1.9 as unsigned) as unsigned;
unsigned
-----
          2
(1 row)

-- mysql5.7: 0      mysql8.0: 18446744073709551614
lightdb@test_m=# select cast(-1.9 as unsigned) as unsigned;
unsigned
-----

### F.53.2.13. AES encryption and decryption

The following AES encryption and decryption and hexadecimal conversion operators are supported:

- hex
- unhex
- aes\_encrypt
- aes\_decrypt

#### F.53.2.13.1. hex

**Description**

The hex function converts bytea data to text.

**Syntax**

hex(data bytea) returns text

**Example**

```
select hex('\x0123456789abcdef');
       hex
-----
0123456789abcdef
(1 row)
```

**F.53.2.13.2. unhex****Description**

The unhex function converts varchar data to bytea.

**Syntax**

unhex(data varchar) returns bytea

**Example**

```
select unhex('0123456789abcdef');
       unhex
-----
\x0123456789abcdef
(1 row)
```

**F.53.2.13.3. aes\_encrypt****Description**

AES encryption function.

**Syntax**

aes\_encrypt(data bytea, key bytea) returns bytea  
aes\_encrypt(data varchar, key varchar) returns bytea

**Example**

```
select aes_encrypt('world', '123456');
       aes_encrypt
-----
\x85400d3bbeeb51259f497fcb4bee03e
(1 row)
```

#### F.53.2.13.4. aes\_decrypt

##### Description

AES decryption function.

##### Syntax

```
aes_decrypt(data bytea, key bytea) returns bytea
aes_decrypt(data varchar, key varchar) returns bytea
aes_decrypt(data bytea, key varchar) returns bytea
```

##### Example

```
select aes_decrypt(aes_encrypt('world', '123456'), '123456');
 aes_decrypt
-----
 \x776f726c64
(1 row)
```

### F.53.3. Queries

The following queries are supported:

- DUAL Table

DUAL table is a virtual table provided by the system. Use when executing SQL where access to a base table is not required, such as when performing tests to get result expressions such as functions and operators.

##### Example

In the following example, the current system date is returned.

```
SELECT CURRENT_DATE "date" FROM DUAL;
   date
-----
2023-05-13
(1 row)
```

## F.54. mysql\_fdw

This LightDB extension implements a Foreign Data Wrapper (FDW) for MySQL<sup>7</sup>.

### F.54.1. Installation

To compile the MySQL<sup>8</sup> foreign data wrapper, MySQL's C client library is needed, and the default version is 8.0.26. This library can be downloaded from the official MySQL website<sup>9</sup>.

The `mysql_config` must also be in the library path, it resides in the MySQL lib directory.

---

<sup>7</sup> <https://www.mysql.com/>

<sup>8</sup> <https://www.mysql.com/>

<sup>9</sup> <https://dev.mysql.com/downloads/mysql/>

```
$ export LD_LIBRARY_PATH=/usr/lib64/mysql/:
$LD_LIBRARY_PATH
```

## F.54.2. Enhancements

The following enhancements are added to the latest version of `mysql_fdw`:

### F.54.2.1. Write-able FDW

The previous version was only read-only, the latest version provides the write capability. The user can now issue an insert, update, and delete statements for the foreign tables using the `mysql_fdw`. It uses the LightDB type casting mechanism to provide opposite type casting between MySQL and LightDB data types.

### F.54.2.2. Connection Pooling

The latest version comes with a connection pooler that utilises the same MySQL database connection for all the queries in the same session. The previous version would open a new MySQL database connection for every query. This is a performance enhancement.

### F.54.2.3. WHERE clause push-down

The latest version will push-down the foreign table where clause to the foreign server. The where condition on the foreign table will be executed on the foreign server hence there will be fewer rows to bring across to LightDB. This is a performance feature.

### F.54.2.4. Column push-down

The previous version was fetching all the columns from the target foreign table. The latest version does the column push-down and only brings back the columns that are part of the select target list. This is a performance feature.

### F.54.2.5. Prepared Statement

(Refactoring for `select` queries to use prepared statement)

The `select` queries are now using prepared statements instead of simple query protocol.

### F.54.2.6. JOIN push-down

`mysql_fdw` now also supports join push-down. The joins between two foreign tables from the same remote MySQL server are pushed to a remote server, instead of fetching all the rows for both the tables and performing a join locally, thereby enhancing the performance. Currently, joins involving only relational and arithmetic operators in join-clauses are pushed down to avoid any potential join failure. Also, only the INNER and LEFT/RIGHT OUTER joins are supported, and not the FULL OUTER, SEMI, and ANTI join. This is a performance feature.

## F.54.3. Usage

The following parameters can be set on a MySQL foreign server object:

- `host`: Address or hostname of the MySQL server. Defaults to `127.0.0.1`
- `port`: Port number of the MySQL server. Defaults to `3306`
- `secure_auth`: Enable or disable secure authentication. Default is `true`

- `init_command`: SQL statement to execute when connecting to the MySQL server.
- `use_remote_estimate`: Controls whether `mysql_fdw` issues remote EXPLAIN commands to obtain cost estimates. Default is `false`
- `reconnect`: Enable or disable automatic reconnection to the MySQL server if the existing connection is found to have been lost. Default is `false`.
- `ssl_key`: The path name of the client private key file.
- `ssl_cert`: The path name of the client public key certificate file.
- `ssl_ca`: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server.
- `ssl_cacpath`: The path name of the directory that contains trusted SSL CA certificate files.
- `ssl_cipher`: The list of permissible ciphers for SSL encryption.
- `fetch_size`: This option specifies the number of rows `mysql_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

The following parameters can be set on a MySQL foreign table object:

- `dbname`: Name of the MySQL database to query. This is a mandatory option.
- `table_name`: Name of the MySQL table, default is the same as foreign table.
- `max_blob_size`: Max blob size to read without truncation.
- `fetch_size`: Same as `fetch_size` parameter for foreign server.

The following parameters need to supplied while creating user mapping.

- `username`: Username to use when connecting to MySQL.
- `password`: Password to authenticate to the MySQL server with.

## F.54.4. Examples

```
-- load extension first time after install
CREATE EXTENSION mysql_fdw;

-- create server object
CREATE SERVER mysql_server
  FOREIGN DATA WRAPPER mysql_fdw
  OPTIONS (host '127.0.0.1', port '3306');

-- create user mapping
CREATE USER MAPPING FOR LightDB
  SERVER mysql_server
  OPTIONS (username 'foo', password 'bar');

-- create foreign table
CREATE FOREIGN TABLE warehouse
(
  warehouse_id int,
  warehouse_name text,
  warehouse_created timestamp
```

```

)
SERVER mysql_server
OPTIONS (dbname 'db', table_name 'warehouse');

-- insert new rows in table
INSERT INTO warehouse values (1, 'UPS', current_date);
INSERT INTO warehouse values (2, 'TV', current_date);
INSERT INTO warehouse values (3, 'Table',
current_date);

-- select from table
SELECT * FROM warehouse ORDER BY 1;

warehouse_id | warehouse_name | warehouse_created
-----+-----+-----
          1 | UPS             | 10-JUL-20 00:00:00
          2 | TV              | 10-JUL-20 00:00:00
          3 | Table           | 10-JUL-20 00:00:00

-- delete row from table
DELETE FROM warehouse where warehouse_id = 3;

-- update a row of table
UPDATE warehouse set warehouse_name = 'UPS_NEW' where
warehouse_id = 1;

-- explain a table with verbose option
EXPLAIN VERBOSE SELECT warehouse_id, warehouse_name
FROM warehouse WHERE warehouse_name LIKE 'TV' limit 1;

                                QUERY PLAN

-----
Limit (cost=10.00..11.00 rows=1 width=36)
  Output: warehouse_id, warehouse_name
  -> Foreign Scan on public.warehouse
(cost=10.00..1010.00 rows=1000 width=36)
  Output: warehouse_id, warehouse_name
  Local server startup cost: 10
  Remote query: SELECT `warehouse_id`, `warehouse_name`
FROM `db`.`warehouse` WHERE ((`warehouse_name` LIKE BINARY 'TV'))

```

## F.55. oracle\_fdw

oracle\_fdw is a LightDB extension that provides a Foreign Data Wrapper for easy and efficient access to Oracle databases, including pushdown of WHERE conditions and required columns as well as comprehensive EXPLAIN support.

oracle\_fdw was written by Laurenz Albe, with notable contributions from Vincent Mora of Oslandia and Tatsuro Yamada of the NTT OSS Center.

Special thanks to Christian Ullrich for ongoing help with Windows.

### F.55.1. Cookbook

This is a simple example how to use oracle\_fdw.

More detailed information will be provided in the sections Options and Usage. You should also read the LightDB documentation on foreign data and the commands referenced there.

For the sake of this example, let's assume you can connect as operating system user `lightdb` (or whoever starts the LightDB server) with the following command:

```
sqlplus orauser/orapwd@//dbserver.mydomain.com:1521/
ORADB
```

That means that the Oracle client and the environment is set up correctly.

We want to access a table defined like this:

```
SQL> DESCRIBE oratab
Name                               Null?    Type
-----
ID                                  NOT NULL NUMBER(5)
TEXT                                VARCHA2(30)
FLOATING                            NOT NULL NUMBER(7,2)
```

Then configure `oracle_fdw` as LightDB superuser like this:

```
ltdb=# CREATE EXTENSION oracle_fdw;
ltdb=# CREATE SERVER oradb FOREIGN DATA WRAPPER
oracle_fdw
        OPTIONS (dbserver '//
dbserver.mydomain.com:1521/ORADB');
```

(You can use other naming methods or local connections, see the description of the option `dbserver` below.)

It is a good idea to use a superuser only where really necessary, so let's allow a normal user to use the foreign server (this is not required for the example to work, but I recommend it):

```
ltdb=# GRANT USAGE ON FOREIGN SERVER oradb TO pguser;
```

Then you can connect to LightDB as `pguser` and define:

```
ltdb=> CREATE USER MAPPING FOR pguser SERVER oradb
        OPTIONS (user 'orauser', password 'orapwd');
```

(You can use external authentication to avoid storing Oracle passwords; see below.)

```
ltdb=> CREATE FOREIGN TABLE oratab (
        id          integer          OPTIONS (key
'true') NOT NULL,
        text        character varying(30),
        floating    double precision NOT NULL
        ) SERVER oradb OPTIONS (schema 'ORAUSER', table
'ORATAB');
```

(Remember that table and schema name -- the latter is optional -- must normally be in uppercase.)

Now you can use the table like a regular LightDB table.

## F.55.2. Objects created by the extension

```
FUNCTION oracle_fdw_handler() RETURNS fdw_handler
FUNCTION oracle_fdw_validator(text[], oid) RETURNS void
```

These functions are the handler and the validator function necessary to create a foreign data wrapper.

```
FOREIGN DATA WRAPPER oracle_fdw
HANDLER oracle_fdw_handler
VALIDATOR oracle_fdw_validator
```

The extension automatically creates a foreign data wrapper named `oracle_fdw`.

Normally that's all you need, and you can proceed to define foreign servers. You can create additional Oracle foreign data wrappers, for example if you need to set the `nls_lang` option (you can alter the existing `oracle_fdw` wrapper, but all modifications will be lost after a dump/restore).

```
FUNCTION oracle_close_connections() RETURNS void
```

This function can be used to close all open Oracle connections in this session. See the Usage section for further description.

```
FUNCTION oracle_diag(name DEFAULT NULL) RETURNS text
```

This function is useful for diagnostic purposes only.

It will return the versions of `oracle_fdw`, LightDB server and Oracle client. If called with no argument or `NULL`, it will additionally return the values of some environment variables used for establishing Oracle connections.

```
FUNCTION oracle_execute(server name, stmt text) RETURNS
void
```

This function can be used to execute arbitrary SQL statements on the remote Oracle server. That will only work with statements that do not return results (typically DDL statements).

Be careful when using this function, since it might disturb the transaction management of `oracle_fdw`. Remember that running a DDL statement in Oracle will issue an implicit `COMMIT`. You are best advised to use this function outside of multi-statement transactions.

## F.55.3. Options

### F.55.3.1. Foreign data wrapper options

(Caution: If you modify the default foreign data wrapper `oracle_fdw`, any changes will be lost upon dump/restore. Create a new foreign data wrapper if you want the options to be persistent. The

SQL script shipped with the software contains a CREATE FOREIGN DATA WRAPPER statement you can use.)

- `nls_lang` (optional)

Sets the NLS\_LANG environment variable for Oracle to this value.

NLS\_LANG is in the form "language\_territory.charset" (for example AMERICAN\_AMERICA.AL32UTF8). This must match your database encoding. When this value is not set, oracle\_fdw will automatically do the right thing if it can and issue a warning if it cannot. Set this only if you know what you are doing. See the Problems section.

### F.55.3.2. Foreign server options

- `dbserver` (required)

The Oracle database connection string for the remote database.

This can be in any of the forms that Oracle supports as long as your Oracle client is configured accordingly.

Set this to an empty string for local ("BEQUEATH") connections.

- `isolation_level` (optional, defaults to `serializable`)

The transaction isolation level to use at the Oracle database.

The value can be `serializable`, `read_committed` or `read_only`.

Note that the Oracle table can be queried more than once during a single LightDB statement (for example, during a nested loop join). To make sure that no inconsistencies caused by race conditions with concurrent transactions can occur, the transaction isolation level must guarantee read stability.

This is only guaranteed with Oracle's SERIALIZABLE or READ ONLY isolation levels.

Unfortunately Oracle's implementation of SERIALIZABLE is rather bad and causes serialization errors (ORA-08177) in unexpected situations, like inserts into the table.

Using READ COMMITTED transactions works around this problem, but there is a risk of inconsistencies. If you want to use it, check your execution plans if the foreign scan could be executed more than once.

- `nchar` (boolean, optional, defaults to off)

Setting this option to on chooses a more expensive character conversion on the Oracle side. This is required if you are using a single-byte Oracle database character set, but have NCHAR or NVARCHAR2 columns containing characters that cannot be represented in the database character set.

Setting `nchar` to on has a noticeable performance impact, and it causes ORA-01461 errors with UPDATE statements that set strings over 2000 bytes (or 16383 if you have MAX\_STRING\_SIZE = EXTENDED). This error seems to be an Oracle bug.

### F.55.3.3. User mapping options

- `user` (required)

The Oracle user name for the session.

Set this to an empty string for external authentication if you don't want to store Oracle credentials in the LightDB database (one simple way is to use an external password store).

- `password` (required)

The password for the Oracle user.

### F.55.3.4. Foreign table options

- `table` (required)

The Oracle table name. This name must be written exactly as it occurs in Oracle's system catalog, so normally consist of uppercase letters only.

To define a foreign table based on an arbitrary Oracle query, set this option to the query enclosed in parentheses, e.g.

```
OPTIONS (table '(SELECT col FROM tab
WHERE val = ''string''))
```

Do not set the `schema` option in this case.

INSERT, UPDATE and DELETE will work on foreign tables defined on simple queries; if you want to avoid that (or confusing Oracle error messages for more complicated queries), use the table option `readonly`.

- `dblink` (optional)

The Oracle database link through which the table is accessed. This name must be written exactly as it occurs in Oracle's system catalog, so normally consist of uppercase letters only.

- `schema` (optional)

The table's schema (or owner). Useful to access tables that do not belong to the connecting Oracle user. This name must be written exactly as it occurs in Oracle's system catalog, so normally consist of uppercase letters only.

- `max_long` (optional, defaults to "32767")

The maximal length of any LONG, LONG RAW and XMLTYPE columns in the Oracle table. Possible values are integers between 1 and 1073741823 (the maximal size of a bytea in LightDB). This amount of memory will be allocated at least twice, so large values will consume a lot of memory.

If `max_long` is less than the length of the longest value retrieved, you will receive the error message `ORA-01406: fetched column value was truncated`.

- `readonly` (optional, defaults to "false")

INSERT, UPDATE and DELETE is only allowed on tables where this option is not set to `yes/on/true`.

- `sample_percent` (optional, defaults to "100")

This option only influences ANALYZE processing and can be useful to ANALYZE very large tables in a reasonable time.

The value must be between 0.000001 and 100 and defines the percentage of Oracle table blocks that will be randomly selected to calculate LightDB table statistics. This is accomplished using the `SAMPLE BLOCK (x)` clause in Oracle.

ANALYZE will fail with `ORA-00933` for tables defined with Oracle queries and may fail with `ORA-01446` for tables defined with complex Oracle views.

- `prefetch` (optional, defaults to "200")

Sets the number of rows that will be fetched with a single round-trip between LightDB and Oracle during a foreign table scan. This is implemented using Oracle row prefetching. The value must be between 0 and 10240, where a value of zero disables prefetching.

Higher values can speed up performance, but will use more memory on the LightDB server.

## F.55.4. Usage

### F.55.4.1. Oracle permissions

The Oracle user will obviously need `CREATE SESSION` privilege and the right to select from the table or view in question.

For `EXPLAIN VERBOSE` the user will also need `SELECT` privileges on `V$SQL` and `V$SQL_PLAN`.

### F.55.4.2. Connections

`oracle_fdw` caches Oracle connections because it is expensive to create an Oracle session for each individual query. All connections are automatically closed when the LightDB session ends.

The function `oracle_close_connections()` can be used to close all cached Oracle connections. This can be useful for long-running sessions that don't access foreign tables all the time and want to avoid blocking the resources needed by an open Oracle connection.

You cannot call this function inside a transaction that modifies Oracle data.

### F.55.4.3. Columns

When you define a foreign table, the columns of the Oracle table are mapped to the LightDB columns in the order of their definition.

`oracle_fdw` will only include those columns in the Oracle query that are actually needed by the LightDB query.

The LightDB table can have more or less columns than the Oracle table. If it has more columns, and these columns are used, you will receive a warning and `NULL` values will be returned.

If you want to `UPDATE` or `DELETE`, make sure that the `key` option is set on all columns that belong to the table's primary key. Failure to do so will result in errors.

### F.55.4.4. Oracle permissions

You must define the LightDB columns with data types that `oracle_fdw` can translate (see the conversion table below). This restriction is only enforced if the column actually gets used, so you can define "dummy" columns for untranslatable data types as long as you don't access them (this trick only works with `SELECT`, not when modifying foreign data). If an Oracle value exceeds the size of the LightDB column (e.g., the length of a `varchar` column or the maximal integer value), you will receive a runtime error.

These conversions are automatically handled by `oracle_fdw`:

Oracle type	Possible LightDB types
CHAR	char, varchar, text

	NCHAR	char, varchar, text
	VARCHAR	char, varchar, text
	VARCHAR2	char, varchar, text,
json		
	NVARCHAR2	char, varchar, text
	CLOB	char, varchar, text,
json		
	LONG	char, varchar, text
	RAW	uuid, bytea
	BLOB	bytea
	BFILE	bytea (read-only)
	LONG RAW	bytea
	NUMBER	numeric, float4, float8,
char, varchar, text		
	NUMBER(n,m)	numeric, float4, float8, int2,
int4, int8,		
		boolean, char,
varchar, text		
	FLOAT	numeric, float4, float8,
char, varchar, text		
	BINARY_FLOAT	numeric, float4, float8,
char, varchar, text		
	BINARY_DOUBLE	numeric, float4, float8,
char, varchar, text		
	DATE	date, timestamp,
timestampz, char, varchar, text		
	TIMESTAMP	date, timestamp,
timestampz, char, varchar, text		
	TIMESTAMP WITH TIME ZONE	date, timestamp,
timestampz, char, varchar, text		
	TIMESTAMP WITH	date, timestamp,
timestampz, char, varchar, text		
	LOCAL TIME ZONE	
	INTERVAL YEAR TO MONTH	interval, char, varchar,
text		
	INTERVAL DAY TO SECOND	interval, char, varchar,
text		
	XMLTYPE	xml, char, varchar, text
	MDSYS.SDO_GEOMETRY	geometry (see "PostGIS
support" below)		

If a NUMBER is converted to a boolean, 0 means false, everything else true

Inserting or updating XMLTYPE only works with values that do not exceed the maximum length of the VARCHAR2 data type (4000 or 32767, depending on the MAX\_STRING\_SIZE parameter).

NCLOB is currently not supported because Oracle cannot automatically convert it to the client encoding.

If you need conversions exceeding the above, define an appropriate view in Oracle or LightDB.

## F.55.4.5. WHERE conditions and ORDER BY clauses

LightDB will use all applicable parts of the WHERE clause as a filter for the scan. The Oracle query that oracle\_fdw constructs will contain a WHERE clause corresponding to these filter criteria whenever such a condition can safely be translated to Oracle SQL. This feature, also known as push-down of WHERE clauses, can greatly reduce the number of rows retrieved from Oracle and may enable Oracle's optimizer to choose a good plan for accessing the required tables.

Similarly, ORDER BY clauses will be pushed down to Oracle wherever possible. Note that no ORDER BY condition that sorts by a character string will be pushed down as the sort orders in LightDB and Oracle cannot be guaranteed to be the same.

To make use of that, try to use simple conditions for the foreign table. Choose LightDB column data types that correspond to Oracle's types, because otherwise conditions cannot be translated.

The expressions `now()`, `transaction_timestamp()`, `current_timestamp`, `current_date` and `localtimestamp` will be translated correctly.

The output of EXPLAIN will show the Oracle query used, so you can see which conditions were translated to Oracle and how.

### F.55.4.6. Joins between foreign tables

`oracle_fdw` can push down joins to the Oracle server, that is, a join between two foreign tables will lead to a single Oracle query that performs the join on the Oracle side.

There are some restrictions when this can happen:

- Both tables must be defined on the same foreign server.
- Joins between three or more tables won't be pushed down.
- The join must be in a SELECT statement.
- `oracle_fdw` must be able to push down all join conditions and WHERE clauses.
- Cross joins without join conditions are not pushed down.
- If a join is pushed down, ORDER BY clauses will not be pushed down

It is important that table statistics for both foreign tables have been collected with ANALYZE for LightDB to determine the best join strategy.

### F.55.4.7. Modifying foreign data

`oracle_fdw` supports INSERT, UPDATE and DELETE on foreign tables. This is allowed by default (also in databases upgraded from an earlier LightDB release) and can be disabled by setting the `readonly` table option.

For UPDATE and DELETE to work, the columns corresponding to the primary key columns of the Oracle table must have the `key` column option set. These columns are used to identify a foreign table row, so make sure that the option is set on all columns that belong to the primary key.

If you omit a foreign table column during INSERT, that column is set to the value defined in the DEFAULT clause on the LightDB foreign table (or NULL if there is no DEFAULT clause). DEFAULT clauses on the corresponding Oracle columns are not used. If the LightDB foreign table does not include all columns of the Oracle table, the Oracle DEFAULT clauses will be used for the columns not included in the foreign table definition.

The RETURNING clause on INSERT, UPDATE and DELETE is supported except for columns with Oracle data types LONG and LONG RAW (Oracle doesn't support these data types in the RETURNING clause).

Triggers on foreign tables are supported. Triggers defined with AFTER and FOR EACH ROW require that the foreign table has no columns with Oracle data type LONG or LONG RAW. This is because such triggers make use of the RETURNING clause mentioned above.

While modifying foreign data works, the performance is not particularly good, specifically when many rows are affected, because (owing to the way foreign data wrappers work) each row has to be treated individually.

Transactions are forwarded to Oracle, so BEGIN, COMMIT, ROLLBACK and SAVEPOINT work as expected. Prepared statements involving Oracle are not supported. See the Internals section for details.

Since oracle\_fdw uses serialized transactions by default, it is possible that data modifying statements lead to a serialization failure:

```
ORA-08177: can't serialize access for this
transaction
```

This can happen if concurrent transactions modify the table and gets more likely in long running transactions. Such errors can be identified by their SQLSTATE (40001). An application using oracle\_fdw should retry transactions that fail with this error.

It is possible to use a different transaction isolation level, see Foreign server options for a discussion.

### F.55.4.8. EXPLAIN

LightDB's EXPLAIN will show the query that is actually issued to Oracle. EXPLAIN VERBOSE will show Oracle's execution plan (that will not work with Oracle server 9i or older, see Problems).

### F.55.4.9. ANALYZE

You can use ANALYZE to gather statistics on a foreign table. This is supported by oracle\_fdw.

Without statistics, LightDB has no way to estimate the row count for queries on a foreign table, which can cause bad execution plans to be chosen.

LightDB will not automatically gather statistics for foreign tables with the autovacuum daemon like it does for normal tables, so it is particularly important to run ANALYZE on foreign tables after creation and whenever the remote table has changed significantly.

Keep in mind that analyzing an Oracle foreign table will result in a full sequential table scan. You can use the table option `sample_percent` to speed this up by using only a sample of the Oracle table.

### F.55.4.10. PostGIS support

The data type `geometry` is only available when PostGIS is installed.

The only supported geometry types are POINT, LINE, POLYGON, MULTIPOINT, MULTILINE and MULTIPOLYGON in two and three dimensions. Empty PostGIS geometries are not supported because they have no equivalent in Oracle Spatial.

NULL values for Oracle SRID will be converted to 0 and vice versa. For other conversions between Oracle SRID and PostGIS SRID, create a file `srid.map` in the LightDB share directory. Each line of this file shall contain an Oracle SRID and the corresponding PostGIS SRID, separated by whitespace. Keep the file small for good performance.

### F.55.4.11. Support for IMPORT FOREIGN SCHEMA

IMPORT FOREIGN SCHEMA is supported to bulk import table definitions for all tables in an Oracle schema.

In addition to the documentation of IMPORT FOREIGN SCHEMA, consider the following:

- IMPORT FOREIGN SCHEMA will create foreign tables for all objects found in ALL\_TAB\_COLUMNS. That includes tables, views and materialized views, but not synonyms.
- These are the supported options for IMPORT FOREIGN SCHEMA:

- `case`: controls case folding for table and column names during import

The possible values are:

- `keep`: leave the names as they are in Oracle, usually in upper case.
- `lower`: translate all table and column names to lower case.
- `smart`: only translate names that are all upper case in Oracle (this is the default).
- `collation`: the collation used for case folding for the `lower` and `smart` options of `case`

The default value is `default` which is the database's default collation. Only collations in the `pg_catalog` schema are supported. See the `collname` values in the `pg_collation` catalog for a list of possible values.

- `dblink`: the Oracle database link through which the schema is accessed

This name must be written exactly as it occurs in Oracle's system catalog, so normally consist of uppercase letters only.

- `readonly`: sets the `readonly` option on all imported tables

See the Options section for details.

- `max_long`: sets the `max_long` option on all imported tables

See the Options section for details.

- `sample_percent`: sets the `sample_percent` option on all imported tables

See the Options section for details.

- `prefetch`: sets the `prefetch` option on all imported tables

See the Options section for details.

- The Oracle schema name must be written exactly as it is in Oracle, so normally in upper case. Since LightDB translates names to lower case before processing, you must protect the schema name with double quotes (for example "SCOTT").
- Table names in the `LIMIT TO` or `EXCEPT` clause must be written as they will appear in LightDB after the case folding described above.

Note that `IMPORT FOREIGN SCHEMA` does not work with Oracle server 8i; see the Problems section for details.

## F.55.5. Internals

`oracle_fdw` sets the `MODULE` of the Oracle session to `LightDB` and the `ACTION` to the backend process number. This can help identifying the Oracle session and allows you to trace it with `DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE`.

`oracle_fdw` uses Oracle's result prefetching to avoid unnecessary client-server round-trips. The `prefetch` row count can be configured with the `prefetch` table option and is set to 200 by default.

Rather than using a `PLAN_TABLE` to explain an Oracle query (which would require such a table to be created in the Oracle database), `oracle_fdw` uses execution plans stored in the library cache. For that, an Oracle query is explicitly described, which forces Oracle to parse the query. The hard part is to find the `SQL_ID` and `CHILD_NUMBER` of the statement in `V$SQL` because the `SQL_TEXT` column contains only the first 1000 bytes of the query. Therefore, `oracle_fdw` adds a comment to the query

that contains an MD5 hash of the query text. This is used to search in V\$SQL. The actual execution plan or cost information is retrieved from V\$SQL\_PLAN.

oracle\_fdw uses transaction isolation level SERIALIZABLE on the Oracle side, which corresponds to LightDB's REPEATABLE READ. This is necessary because a single LightDB statement can lead to multiple Oracle queries (e.g. during a nested loop join) and the results need to be consistent.

Unfortunately the Oracle implementation of SERIALIZABLE has certain quirks; see the Problems section for more.

The Oracle transaction is committed immediately before the local transaction commits, so that a completed LightDB transaction guarantees that the Oracle transaction has completed. However, there is a small chance that the LightDB transaction cannot complete even though the Oracle transaction is committed. This cannot be avoided without using two-phase transactions and a transaction manager, which is beyond what a foreign data wrapper can reasonably provide.

Prepared statements involving Oracle are not supported for the same reason.

## F.55.6. Problems

### F.55.6.1. Encoding

Characters stored in an Oracle database that cannot be converted to the LightDB database encoding will silently be replaced by `replacement_characters`, typically a normal or inverted question mark, by Oracle. You will get no warning or error messages.

If you use a LightDB database encoding that Oracle does not know (currently, these are EUC\_CN, EUC\_KR, LATIN10, MULE\_INTERNAL, WIN874 and SQL\_ASCII), non-ASCII characters cannot be translated correctly. You will get a warning in this case, and the characters will be replaced by replacement characters as described above.

You can set the `nls_lang` option of the foreign data wrapper to force a certain Oracle encoding, but the resulting characters will most likely be incorrect and lead to LightDB error messages. This is probably only useful for SQL\_ASCII encoding if you know what you are doing. See the Options section.

### F.55.6.2. Limited functionality in old Oracle versions

- The definition of the Oracle system catalogs V\$SQL and V\$SQL\_PLAN has changed with Oracle 10.1. Using EXPLAIN VERBOSE with older Oracle server versions will result in errors like:

```
ERROR: error describing query:
OCIStmtExecute failed to execute
      remote query for sql_id
DETAIL:  ORA-00904: "LAST_ACTIVE_TIME":
invalid identifier
```

There is no plan to fix this, since Oracle 9i has been out of Extended Support since 2010 and the functionality is not essential.

- IMPORT FOREIGN SCHEMA throws the following error with Oracle server 8i:

```
ERROR: error importing foreign schema:
OCIStmtExecute failed to execute
      column query
DETAIL:  ORA-00904: invalid column name
```

This is because the view `ALL_TAB_COLUMNS` lacks the column `CHAR_LENGTH`, which was added in Oracle 9i.

### F.55.6.3. Serialization errors

In Oracle 11.2 or above, inserting the first row into a newly created Oracle table with `oracle_fdw` will lead to a serialization error.

This is because of an Oracle feature called `deferred segment creation` which defers allocation of storage space for a new table until the first row is inserted. This causes a serialization failure with serializable transactions (see document 1285464.1 in Oracle's knowledge base).

This is no serious problem; you can work around it by either ignoring that first error or creating the table with `SEGMENT CREATION IMMEDIATE`.

A much nastier problem is that concurrent inserts can sometimes cause serialization errors when an index page is split concurrently with a modifying serializable transaction (see Oracle document 160593.1).

Oracle claims that this is not a bug, and the suggested solution is to retry the transaction that got a serialization error.

### F.55.6.4. Oracle bugs

This is a list of Oracle bugs that have affected `oracle_fdw` in the past.

Bug 2728408 can cause `ORA-8177 cannot serialize access for this transaction` even if no modification of remote data is attempted.

It can occur with Oracle server 8.1.7.4 (install one-off patch 2728408) or Oracle server 9.2 (install Patch Set 9.2.0.4 or better).

## F.56. orafce

`orafce` - Oracle's compatibility functions and packages.

### F.56.1. Features Compatible with Oracle Databases

Features compatible with Oracle databases are provided. These features enable you to easily migrate to LightDB and reduce the costs of reconfiguring applications. The table below lists features compatible with Oracle databases.

**Table F.86. Data type**

Item	Overview
<code>VARCHAR2</code>	Variable-length character data type
<code>NVARCHAR2</code>	Variable-length national character data type
<code>DATE</code>	Data type that stores date and time
<code>NUMBER</code>	<code>NUMBER</code> is an alias for <code>NUMERIC</code>
<code>CLOB</code>	stores single-byte and multibyte character data and has mostly same functionality with <code>text</code> data type.
<code>BLOB</code>	stores unstructured binary large objects and has mostly same functionality with <code>'bytea'</code> data type.

Item	Overview
RAW	Variable-length hex data type .
PLS_INTEGER	A PL/SQL data type used for storing signed integers.
BINARY_FLOAT	32-bit floating point number. This data type requires 4 bytes.
BINARY_DOUBLE	64-bit floating point number. This data type requires 8 bytes.
XMLType	Variable-length xml data type .

varchar2 and nvarchar2 is config in priority between varchar and char, after create orafce extensin, the priority is :

numeric > double precision > real > bigint > integer > smallint > text > varchar > varchar2 > nvarchar2 > char

**Table F.87. SQL Queries**

Item	Overview
DUAL table	Table provided by the system

**Table F.88. Mathematical Functions**

Item	Overview	Parallel attribute
BIN_TO_NUM	Converts a bit vector to its equivalent number	Safe
BITAND	Performs a bitwise AND operation	Safe
BITOR	Performs a bitwise OR operation	Safe
BITXOR	Performs a bitwise XOR operation	Safe
COSH	Calculates the hyperbolic cosine of a number	Safe
MOD	Returns the remainder (modulus) of argument 1 divided by argument 2.	Safe
REMAINDER	Returns the remainder of n2 divided by n1	Safe
ROUND_TIES_TO_EVEN	Returns n rounded to integer places	Safe
SINH	Calculates the hyperbolic sine of a number	Safe
TANH	Calculates the hyperbolic tangent of a number	Safe
CEIL	Returns the smallest integer(type interval will extract the days to number first) that is greater than or equal to a number	Safe

**Table F.89. String Functions**

<b>Item</b>	<b>Overview</b>	<b>Parallel attribute</b>
INSTR	Returns the position of a substring in a string	Safe
INSTRB	Returns the position in the string that is the first byte of a specified occurrence of the substring	Safe
LENGTH	Returns the length of a string in number of characters	Safe
LENGTHB	Returns the length of a string in number of bytes	Safe
LPAD	Left-pads a string to a specified length with a sequence of characters	Safe
LTRIM	Removes the specified characters from the beginning of a string	Safe
NLSSORT	Returns a byte string used to sort strings in linguistic sort sequence based on locale	Safe
REGEXP_COUNT	searches a string for a regular expression, and returns a count of the matches	Safe
REGEXP_INSTR	returns the beginning or ending position within the string where the match for a pattern was located	Safe
REGEXP_LIKE	condition in the WHERE clause of a query, causing the query to return rows that match the given pattern	Safe
REGEXP_SUBSTR	returns the string that matches the pattern specified in the call to the function	Safe
REGEXP_REPLACE	returns the string that matches the pattern specified in the call to the function	Safe
REPLACE	REPLACE returns string with every occurrence of search_string replaced with replacement_string	Safe
RPAD	Right-pads a string to a specified length with a sequence of characters	Safe
RTRIM	Removes the specified characters from the end of a string	Safe
SOUNDEX	Returns a character string containing the phonetic representation of char.	Safe

Item	Overview	Parallel attribute
SUBSTR	Extracts part of a string using characters to specify position and length	Safe
SUBSTRB	Extracts part of a string using bytes to specify position and length	Safe
GUID	Return UUID	Safe
CONCAT	concatenate two strings	Safe
UPPER	make all letters uppercase	Safe

**Table F.90. Date/Time Functions**

Item	Overview	Parallel attribute
ADD_MONTHS	Adds months to a date	Safe
DBTIMEZONE	Returns the value of the database time zone	Safe
LENGTHB	Returns the length of a string in number of bytes	Safe
LAST_DAY	Returns the last day of the month in which the specified date falls	Safe
LTRIM	Removes the specified characters from the beginning of a string	Safe
MONTHS_BETWEEN	Returns the number of months between two dates	Safe
NEXT_DAY	Returns the date of the first instance of a particular day of the week that follows the specified date	Safe
ROUND	Rounds a date	Safe
SESSIONTIMEZONE	Returns the time zone of the session	Safe
SYSDATE	Returns the system date	Safe
TRUNC	Truncates a date	Safe
TZ_OFFSET	Returns the time zone offset	Safe

**Table F.91. Data Type Formatting Functions**

Item	Overview	Parallel attribute
CONVERT	Converts a character string from one character set to another.	Safe
NUMTOYMINTERVAL	Converts number to an INTERVAL YEAR TO MONTH literal	Safe
TO_BLOB(raw)	Converts RAW values to BLOB values.	Safe
TO_CHAR	Converts a value to a string	Safe

Item	Overview	Parallel attribute
TO_DATE	Converts a string to a date in accordance with the specified format	Safe
TO_MULTI_BYTE	Converts a single-byte string to a multibyte string	Safe
TO_NUMBER	Converts a value to a number in accordance with the specified format	Safe
TO_SINGLE_BYTE	Converts a multibyte string to a single-byte string	Safe
TO_CLOB	Converts a string or a number to clob	

**Table F.92. Conditional Expressions**

Item	Overview	Parallel attribute
DECODE	Compares values, and if they match, returns a corresponding value	Safe
LNNVL	Evaluates if a value is false or unknown	Safe
NANVL	Returns a substitute value when a value is not a number (NaN)	Safe
NVL	Returns a substitute value when a value is NULL	Safe
NVL2	Returns a substitute value based on whether a value is NULL or not NULL	Safe

**Table F.93. Aggregate Functions**

Item	Overview	Parallel attribute
ANY_VALUE	Returns a single non-deterministic value of expr.	Unsafe
BIT_AND_AGG	Returns the result of a bitwise AND operation	Unsafe
BIT_OR_AGG	Returns the result of a bitwise OR operation	Unsafe
BIT_XOR_AGG	Returns the result of a bitwise XOR operation	Unsafe
KURTOSIS_POP	Used to determine the characteristics of outliers in a given distribution	Unsafe
KURTOSIS_SAMP	Used to determine the characteristics of outliers in a given distribution	Unsafe
LISTAGG	Returns a concatenated, delimited list of string values	Unsafe
MEDIAN	Calculates the median of a set of values	Unsafe

Item	Overview	Parallel attribute
SKEWNESS_POP	Used to determine symmetry in a given distribution	Unsafe
SKEWNESS_SAMP	Used to determine symmetry in a given distribution	Unsafe

**Table F.94. Functions that return internal information**

Item	Overview	Parallel attribute
DUMP	Returns internal information of a value	Safe
NLS_CHARSET_ID	Returns the character set ID number corresponding to character set name string.	Safe
NLS_CHARSET_NAME	Returns the name of the character set corresponding to ID number number.	Safe
SYS_CONTEXT	Returns the value of parameter associated with the context namespace at the current instant	Safe
USERENV	Returns the value of parameter associated with the context 'USERENV' at the current session	Safe

**Table F.95. SQL Operators**

Item	Overview
Datetime operator	Datetime operator for the DATE type

**Table F.96. Other functions**

Item	Overview	Parallel attribute
EMPTY_CLOB	Return an empty CLOB	Safe
EMPTY_BLOB	Return an empty BLOB	Safe
ORA_HASH	ORA_HASH is a function that computes a hash value for a given expression	Safe
VSIZE	Returns the number of bytes in the internal representation of expr	Safe
DEPS_SAVE_AND_DROP_DEPENDENCIES	Save and drop dependencies for table	Unsafe
DEPS_RESTORE_DEPENDENCIES	Restore dependencies for table	Unsafe
PLVSTR.IS_PREFIX	Return true if a is the prefix of b.	Safe
plvdate.isleapyear	Return true if the date is a leap year.	

**Table F.97. Packages**

<b>Item</b>	<b>Overview</b>
DBMS_ALERT	Sends alerts to multiple sessions
DBMS_ASSERT	Validates the properties of an input value
DBMS_LOB	Some functions compatible with DBMS_LOB package.
DBMS_OUTPUT	Sends messages to clients
DBMS_PIPE	Creates a pipe for inter-session communication
DBMS_RANDOM	Generates random numbers
DBMS_UTILITY	Provides various utilities
DBMS_JOB	Schedules and manages jobs in the It_cron
DBMS_LOCK	Provides an interface to Lock Management services
DBMS_METADATA	Provides a way for you to retrieve metadata from the database dictionary
DBMS_OBFUSCATION_TOOLKIT	Enables an application to encrypt data using either the Data Encryption Standard (DES) or the Triple DES algorithms
DBMS_SNAPSHOT	Enables you to refresh snapshots(MVIEW)
UTL_FILE	Enables text file operations
UTL_RAW	Provides SQL functions for manipulating RAW datatypes
UTL_URL	Has two functions that provide escape and unescape mechanisms for URL characters
UTL_ENCODE	Provides functions that encode RAW data into a standard encoded format

**Table F.98. System View**

<b>Item</b>	<b>Overview</b>
DBA_SEQUENCES ALL_SEQUENCES USER_SEQUENCES	Describes sequences
DBA_SYNONYMS ALL_SYNONYMS USER_SYNONYMS	Describes the synonyms, empty now
DBA_TAB_COLS ALL_TAB_COLS USER_TAB_COLS COLS DBA_TAB_COLUMNS ALL_TAB_COLUMNS	Describes the columns of tables, views

Item	Overview
USER_TAB_COLUMNS	
DBA_TAB_COL_STATISTICS ALL_TAB_COL_STATISTICS USER_TAB_COL_STATISTICS	Contains column statistics and histogram information extracted from "[DBA/ALL/USER]_TAB_COLUMNS"
DBA_OBJECTS ALL_OBJECTS USER_OBJECTS OBJ	Describes objects
DBA_CATALOG ALL_CATALOG USER_CATALOG	Lists tables, views, and sequences
DICTIONARY DICT	Contains descriptions of data dictionary tables and views.
DBA_DEPENDENCIES ALL_DEPENDENCIES USER_DEPENDENCIES	Describes dependencies between objects
DBA_SOURCE ALL_SOURCE USER_SOURCE	Describes the text source of stored objects
DBA_PROCEDURES ALL_PROCEDURES USER_PROCEDURES	Lists functions and procedures
DBA_TRIGGERS ALL_TRIGGERS USER_TRIGGERS	Describes triggers
DBA_TRIGGER_COLS ALL_TRIGGER_COLS USER_TRIGGER_COLS	Describes the use of columns in triggers
DBA_TYPES ALL_TYPES USER_TYPES	Describes object types
DBA_CONSTRAINTS ALL_CONSTRAINTS USER_CONSTRAINTS	Describes constraint definitions

<b>Item</b>	<b>Overview</b>
DBA_CONS_COLUMNS ALL_CONS_COLUMNS USER_CONS_COLUMNS	Describes columns that are specified in constraints
DBA_VIEWS ALL_VIEWS USER_VIEWS	Describes views
DBA_TABLES ALL_TABLES USER_TABLES TABS DBA_ALL_TABLES ALL_ALL_TABLES USER_ALL_TABLES TAB	Describes object tables and relational tables
DBA_TAB_STATISTICS ALL_TAB_STATISTICS USER_TAB_STATISTICS	Displays optimizer statistics for tables
DBA_TAB_COMMENTS ALL_TAB_COMMENTS USER_TAB_COMMENTS	Displays comments on tables and views
DBA_COL_COMMENTS ALL_COL_COMMENTS USER_COL_COMMENTS	Displays comments on the columns of tables and views
DBA_TAB_MODIFICATIONS ALL_TAB_MODIFICATIONS USER_TAB_MODIFICATIONS	Describes modifications to all tables
DBA_INDEXES ALL_INDEXES USER_INDEXES IND	Describes indexes
DBA_INDEX_USAGE ALL_INDEX_USAGE USER_INDEX_USAGE	Displays cumulative statistics for each index.

<b>Item</b>	<b>Overview</b>
DBA_IND_COLUMNS ALL_IND_COLUMNS USER_IND_COLUMNS	Describes the columns of indexes on tables
DBA_IND_EXPRESSIONS ALL_IND_EXPRESSIONS USER_IND_EXPRESSIONS	Describes the expressions of function-based indexes
DBA_IND_STATISTICS ALL_IND_STATISTICS USER_IND_STATISTICS	Displays optimizer statistics for indexes
DBA_USERS ALL_USERS USER_USERS	Describes users
DBA_ROLES	Describes all roles in the database
DBA_ROLE_PRIVS USER_ROLE_PRIVS	Describes the roles granted to users and roles
PRODUCT_COMPONENT_VERSION	Contains version and status information for component products
PLAN_TABLE	PLAN_TABLE is automatically created as a global temporary table to hold the output of an EXPLAIN PLAN statement for all users, empty now
DBA_DATA_FILES	Describes database files
DBA_JOBS ALL_JOBS USER_JOBS	Describes jobs
DBA_JOBS_RUNNING	Lists all jobs that are currently running in the instance
DBA_MVIEWS ALL_MVIEWS USER_MVIEWS	Describes materialized views
DBA_MVIEW_LOGS ALL_MVIEW_LOGS USER_MVIEW_LOGS	Describes all materialized view logs now it is empty
DBA_MVIEW_COMMENTS ALL_MVIEW_COMMENTS USER_MVIEW_COMMENTS	Displays comments on the materialized views
DBA_TABLESPACES	Describes tablespaces

Item	Overview
USER_TABLESPACES	
NLS_DATABASE_PARAMETERS NLS_INSTANCE_PARAMETERS NLS_SESSION_PARAMETERS	Lists NLS parameters
DBA_SEGMENTS USER_SEGMENTS	Describes the storage allocated for segments
DBA_PART_TABLES ALL_PART_TABLES USER_PART_TABLES	Displays the object-level partitioning information for the partitioned tables
DBA_TAB_PARTITIONS ALL_TAB_PARTITIONS USER_TAB_PARTITIONS	Displays partition-level partitioning information, partition storage parameters, and partition statistics
DBA_TAB_SUBPARTITIONS ALL_TAB_SUBPARTITIONS USER_TAB_SUBPARTITIONS	Displays information for all subpartitions
DBA_PART_KEY_COLUMNS ALL_PART_KEY_COLUMNS USER_PART_KEY_COLUMNS	Describes the partitioning key columns for the partitioned objects
DBA_SUBPART_KEY_COLUMNS ALL_SUBPART_KEY_COLUMNS USER_SUBPART_KEY_COLUMNS	Displays subpartitioning key columns for composite-partitioned tables (and local indexes on composite-partitioned tables)
DBA_IND_PARTITIONS ALL_IND_PARTITIONS USER_IND_PARTITIONS	Describes index partitions
DBA_PART_INDEXES ALL_PART_INDEXES USER_PART_INDEXES	Displays the object-level partitioning information for the partitioned indexes
COL	Describes the columns of tables, views

Views starting with DBA show something in the database. Views starting with ALL is currently the same as Views starting with DBA, and no permission verification is done like oracle. now. Views starting with USER show something owned by the current user (actually is current schema. in oracle, User and schema are one-to-one correspondence).

#### Numeric implicit cast with Boolean

oracle supports type NUMERIC implicit cast to BOOL , and vice versa.

#### Example

```
CREATE TABLE test(v1 BOOLEAN, v2 NUMERIC);

-- numeric implicit cast to boolean
-- boolean implicit cast to numeric
INSERT INTO test(v1, v2) VALUES(1.1, true);
SELECT * FROM test WHERE v2 = true;
```

## F.56.2. Notes on Using orafce

Orafce is defined as user-defined functions in the "public" schema created by default when database clusters are created, so they can be available for all users without the need for special settings. For this reason, ensure that "public" (without the double quotation marks) is included in the list of schema search paths specified in the search\_path parameter.

The following features provided by orafce are implemented in LightDB and orafce using different external specifications. In the default configuration of LightDB, the standard features of LightDB take precedence.

**Table F.99. Data type**

Item	Standard feature of LightDB	Compatibility feature added by orafce
DATE	Stores date only.	Stores date and time.

**Table F.100. Function**

Item	Standard feature of LightDB	Compatibility feature added by orafce
LENGTH	If the string is CHAR type, trailing spaces are not included in the length.	If the string is CHAR type, trailing spaces are included in the length.
SUBSTR	If 0 or a negative value is specified for the start position, simply subtracting 1 from the start position, the position will be shifted to the left, from where extraction will start.	- If 0 is specified for the start position, extraction will start from the beginning of the string.  - If a negative value is specified for the start position, extraction will start from the position counted from the end of the string.
LPAD RPAD	- If the string is CHAR type, trailing spaces are removed and then the value is padded.  - The result length is handled as a number of characters.	- If the string is CHAR type, the value is padded without removing trailing spaces.  - The result length is based on the width of the displayed string. Therefore, fullwidth characters are handled using a width of 2, and halfwidth characters are handled using a width of 1.
LTRIM RTRIM	If the string is CHAR type, trailing spaces are removed and then the value is removed.	If the string is CHAR type, the value is removed without removing trailing spaces.

Item	Standard feature of LightDB	Compatibility feature added by orafce
BTRIM (*1)		
TO_DATE	The data type of the return value is DATE.	The data type of the return value is TIMESTAMP.

\*1: BTRIM does not exist for Oracle databases, however, an external specification different to LightDB is implemented in orafce to align with the behavior of the TRIM functions.

Also, the following features cannot be used in the default configuration of LightDB.

### Table F.101. Function

Feature
SYSDATE
DBTIMEZONE
SESSIONTIMEZONE
TO_CHAR (date/time value)

### Table F.102. Operator

Feature
Datetime operator

To use these features, set "oracle" and "pg\_catalog" in the "search\_path" parameter of lightdb.conf. You must specify "oracle" before "pg\_catalog" when doing this.

```
search_path = '$user', public, oracle, pg_catalog'
```

### Information

- The search\_path parameter specifies the order in which schemas are searched. Each feature compatible with Oracle databases is defined in the oracle schema.
- It is recommended to set search\_path in lightdb.conf. In this case, it will be effective for each instance.
- The configuration of search\_path can be done at the user level or at the database level. Setting examples are shown below.
- If the standard features of LightDB take precedence, and features that cannot be used with the default configuration of LightDB are not required, it is not necessary to change the settings of search\_path.
- Example of setting at the user level. This can be set by executing an SQL command. In this example, user1 is used as the username.

```
ALTER USER user1 SET search_path =
'$user', public, oracle, pg_catalog;
```

- Example of setting at the database level. This can be set by executing an SQL command. In this example, db1 is used as the database name. You must specify "oracle" before "pg\_catalog".

```
ALTER DATABASE db1 SET search_path =
"$user",public,oracle,pg_catalog;
```

See

- Refer to "Server Administration" > "Client Connection Defaults" > "Statement Behavior" in the LightDB Documentation for information on search\_path.
- Refer to "Reference" > "SQL Commands" in the LightDB Documentation for information on ALTER USER and ALTER DATABASE.

## F.56.3. Data Types

The following data types are supported:

- VARCHAR2
- NVARCHAR2
- DATE
- RAW
- PLS\_INTEGER
- BINARY\_FLOAT
- BINARY\_DOUBLE
- XMLType

### F.56.3.1. VARCHAR2

**Syntax**

Specify the VARCHAR2 type as follows.

**Table F.103. VARCHAR2 Syntax**

Data type syntax	Explanation
VARCHAR2( <i>len</i> [ <i>byte char</i> ])	String with a variable length up to <i>len</i> characters. For <i>len</i> , specify an integer greater than 0. If <i>len</i> is omitted, the string can be any length. Since 23.1, LightDB implements this syntax-sugar for compatibility with oracle varchar2 types. The keyword <i>byte</i> or <i>char</i> after <i>len</i> is optional, it is only compatible for oracle syntax, internal implementation is the same as only <i>len</i> without <i>byte</i> or <i>char</i> keyword.

**General rules**

- VARCHAR2 is a character data type. Specify the number of characters for the length.
- Strings are of variable length. The specified value will be stored as is. The upper limit for this data type is approximately one gigabyte.

**Note**

The VARCHAR2 type does not support collating sequences. Therefore, the following error occurs when a collating sequence like that of an ORDER BY clause is required. At this time, the following HINT will prompt to use a COLLATE clause, however, because collating sequences are not supported, it is not possible to use this clause.

```

ERROR:   could not determine which collation to use for string
comparison
HINT:    Use the COLLATE clause to set the collation explicitly.
    
```

If the error shown above is displayed, explicitly cast the column to VARCHAR or TEXT type.

**Example**

```

lightdb@postgres=# create table t1(name varchar2(10));
CREATE TABLE
lightdb@postgres=#
lightdb@postgres=# \d+ t1
                                Table "public.t1"
Column |      Type      | Collation | Nullable | Default | Storage |
Stats target | Description
-----+-----+-----+-----+-----+-----+
name    | varchar2(10)   |           |          |         | plain   |
        |                |           |          |         |         |
Access method: heap
    
```

```

lightdb@postgres=#
lightdb@postgres=# create table t2(name varchar2(10 byte));
CREATE TABLE
lightdb@postgres=#
lightdb@postgres=# \d+ t2
                                Table "public.t2"
Column |      Type      | Collation | Nullable | Default | Storage |
Stats target | Description
-----+-----+-----+-----+-----+
name    | varchar2(10)   |           |          |         | plain   |

lightdb@postgres=#
    
```

## F.56.3.2. NVARCHAR2

### Syntax

Specify the NVARCHAR2 type as follows.

**Table F.104. NVARCHAR2 Syntax**

Data type syntax	Explanation
NVARCHAR2( <i>len</i> )	National character string with a variable length up to <i>len</i> characters. For <i>len</i> , specify an integer greater than 0. If <i>len</i> is omitted, the string can be any length.

### General rules

- NVARCHAR2 is a national character data type. Specify the number of characters for the length.
- Strings are of variable length. The specified value will be stored as is. The upper limit for this data type is approximately one gigabyte.

### Note

The NVARCHAR2 type does not support collating sequences. Therefore, the following error occurs when a collating sequence like that of an ORDER BY clause is required. At this time, the following HINT will prompt to use a COLLATE clause, however, because collating sequences are not supported, it is not possible to use this clause.

```

ERROR:   could not determine which collation to use for string
comparison
HINT:    Use the COLLATE clause to set the collation explicitly.

```

If the error shown above is displayed, explicitly cast the column to NCHAR VARYING or TEXT type.

## F.56.3.3. DATE

### Syntax

Specify the DATE type as follows.

**Table F.105. DATE Syntax**

Data type syntax	Explanation
DATE	Stores date and time

### General rules

- DATE is a date/time data type.
- Date and time are stored in DATE. The time zone is not stored.

### Note

If the DATE type of orafce is used in DDL statements such as table definitions, always set search\_path before executing a DDL statement. Even if search\_path is changed after definition, the data type will be the DATE type of LightDB.

### Information

The DATE type of orafce is equivalent to the TIMESTAMP type of LightDB. Therefore, of the existing functions of LightDB, functions for which the data type of the argument is TIMESTAMP can be used.

### F.56.3.4. RAW

#### Syntax

Specify the RAW type as follows.

**Table F.106. RAW Syntax**

RAW type syntax	Explanation
RAW(len)	Store variable-length Binary data. External representation is hexadecimal. The len is only used to be compatible with oracle, it has no effect. the binary data can be any length.

#### General rules

- RAW is a variable-length hex data type.
- Hex strings are of variable length. The specified value will be stored as binary data. The upper limit for this data type is approximately one gigabyte.

### F.56.3.5. PLS\_INTEGER

#### Syntax

Specify the PLS\_INTEGER type as follows.

**Table F.107. PLS\_INTEGER Syntax**

PLS_INTEGER type syntax	Explanation
PLS_INTEGER	The PLS_INTEGER data type stores signed integers in the range -2,147,483,648 through 2,147,483,647, represented in 32 bits.

#### General rules

- PLS\_INTEGER behaves like int4.

### F.56.3.6. BINARY\_FLOAT

#### Syntax

Specify the BINARY\_FLOAT type as follows.

**Table F.108. BINARY\_FLOAT Syntax**

BINARY_FLOAT type syntax	Explanation
BINARY_FLOAT	BINARY_FLOAT is a 32-bit, single-precision floating-point number data type. Each BINARY_FLOAT value requires 4 bytes.

#### General rules

- BINARY\_FLOAT behaves like float4 in lightdb.
- The same as oracle, it follows the IEEE754 standard.

#### Example

```
lightdb@test_o=# create table t1(key1 binary_float);
CREATE TABLE
lightdb@test_o=# \d+ t1

                                Table "public.t1"
 Column |      Type      | Collation | Nullable | Default | Storage
 | Sta
ts target | Description
-----+-----+-----+-----+-----+-----
+----
-----+-----
 key1   | binary_float |           |          |         | plain  |
      |
Access method: heap
lightdb@test_o=# insert into t1
 values(123456789012345678901234567890123456789);
INSERT 0 1
lightdb@test_o=# insert into t1 values('infinity');
INSERT 0 1
lightdb@test_o=# insert into t1 values('NaN');
INSERT 0 1
lightdb@test_o=# select * from t1;
 key1
-----
 1.2345679e+38
      Infinity
      NaN
(3 rows)
```

### F.56.3.7. BINARY\_DOUBLE

#### Syntax

Specify the BINARY\_DOUBLE type as follows.

**Table F.109. BINARY\_DOUBLE Syntax**

BINARY_DOUBLE type syntax	Explanation
BINARY_DOUBLE	BINARY_DOUBLE is a 64-bit, double-precision floating-point number data type. Each BINARY_DOUBLE value requires 8 bytes.

#### General rules

- BINARY\_DOUBLE behaves like float8 in lightdb.
- The same as oracle, it follows the IEEE754 standard.

#### Example

```
lightdb@test_o=# create table t1(key1 binary_double);
CREATE TABLE
lightdb@test_o=# \d+ t1

                                Table "public.t1"
 Column |      Type      | Collation | Nullable | Default | Storage
 | Sta
ts target | Description
-----+-----+-----+-----+-----+-----
+----
-----+-----
 key1   | binary_double |           |          |         | plain  |
      |
Access method: heap
lightdb@test_o=# insert into t1
 values(123456789012345678901234567890123456789);
INSERT 0 1
lightdb@test_o=# insert into t1 values('infinity');
INSERT 0 1
lightdb@test_o=# insert into t1 values('NaN');
INSERT 0 1
lightdb@test_o=# select * from t1;
 key1
-----
 1.2345679e+38
      Infinity
      NaN
(3 rows)
```

```

ts target | Description
-----+-----+-----+-----+-----
+----
-----+-----
key1      | binary_double |           |           | plain
|
|
Access method: heap
lightdb@test_o=# insert into t1
  values(123456789012345678901234567890123456789);
INSERT 0 1
lightdb@test_o=# insert into t1 values('infinity');
INSERT 0 1
lightdb@test_o=# insert into t1 values('NaN');
INSERT 0 1
lightdb@test_o=# select * from t1;
           key1
-----
1.2345678901234568e+38
                    Infinity
                    NaN
(3 rows)

```

### F.56.3.8. XMLType

#### Syntax

Specify the XMLType type as follows.

**Table F.110. XMLType Syntax**

XMLType syntax	Explanation
XMLType	XMLType is an object type, that can be used to store XML data.

#### General rules

- XMLType is xml data type.
- Implicit conversions between oracle.XMLType and pg\_catalog.xml are supported.

#### member function

- function getClobVal() return CLOB  
returns XML as text

#### Example

```

lightdb@postgres=# create database test_oracle
lightdb_syntax_compatible_type oracle;
CREATE DATABASE

lightdb@postgres=# \c test_oracle
You are now connected to database "test_oracle" as user
"lightdb".

```

```

compatible type: oracle

lightdb@test_oracle=# select dbms_output.serveroutput(true);
serveroutput
-----

(1 row)

lightdb@test_oracle=# CREATE TABLE xml_table (id NUMBER,
xml_column XMLType );
CREATE TABLE

lightdb@test_oracle=# INSERT INTO xml_table (id, xml_column)
VALUES (1, XMLType('<root><name>John</name></root>'));
INSERT 0 1

lightdb@test_oracle=# DECLARE
lightdb@test_oracle$$  v_clob CLOB;
lightdb@test_oracle$$ BEGIN
lightdb@test_oracle$$  SELECT XMLType.getClobVal(xml_column)
lightdb@test_oracle$$  INTO v_clob
lightdb@test_oracle$$  FROM xml_table
lightdb@test_oracle$$  WHERE id = 1;
lightdb@test_oracle$$  DBMS_OUTPUT.PUT_LINE('CLOB value: ' ||
v_clob);
lightdb@test_oracle$$ END;
lightdb@test_oracle$$ /
CLOB value: <root><name>John</name></root>
DO

lightdb@test_oracle=# DECLARE
lightdb@test_oracle$$  xml_data XMLType;
lightdb@test_oracle$$  clob_data CLOB;
lightdb@test_oracle$$ BEGIN
lightdb@test_oracle$$  xml_data := XMLType('<root><name>John
Doe</name></root>');
lightdb@test_oracle$$  clob_data := xml_data.getClobVal();
lightdb@test_oracle$$  DBMS_OUTPUT.PUT_LINE(clob_data);
lightdb@test_oracle$$ END;
lightdb@test_oracle$$ /
<root><name>John Doe</name></root>
DO

lightdb@test_oracle=# SELECT XMLType.getClobVal(xml_column)
from xml_table;
getclobval
-----
<root><name>John</name></root>
(1 row)

```

## F.56.4. Queries

The following queries are supported:

- DUAL Table

DUAL table is a virtual table provided by the system. Use when executing SQL where access to a base table is not required, such as when performing tests to get result expressions such as functions and operators.

**Example**

In the following example, the current system date is returned.

```
SELECT CURRENT_DATE "date" FROM DUAL;
      date
-----
2013-05-14
(1 row)
```

## F.56.5. SQL Functions Reference

### F.56.5.1. Mathematical Functions

The following mathematical functions are supported:

- BIN\_TO\_NUM
- BITAND
- BITOR
- BITXOR
- COSH
- MOD
- REMAINDER
- ROUND\_TIES\_TO\_EVEN
- SINH
- TANH

#### F.56.5.1.1. BIN\_TO\_NUM

**Description**

BIN\_TO\_NUM converts a bit vector to its equivalent number.

**Syntax**

```
BIN_TO_NUM(VARIADIC integer []) returns int
```

**General rules**

- Each argument to this function represents a bit in the bit vector.
- This function takes as arguments any integer data type, or any noninteger data type that can be implicitly converted to integer.

- BIN\_TO\_NUM is useful in data warehousing applications for selecting groups of interest from a materialized view using grouping sets.

**Note**

- If using BIN\_TO\_NUM for converting, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using oracle" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
SELECT BIN_TO_NUM(1,0,1,0) FROM DUAL;
   bin_to_num
-----
           10
(1 row)
```

### F.56.5.1.2. BITAND

**Description**

Performs a bitwise AND operation.

**Syntax**

```
BITAND(int1 integers, int2 integers) returns bigint
```

**General rules**

- BITAND performs an AND operation on each bit of two integers, and returns the result.
- Specify integer type values.
- The data type of the return value is BIGINT.

**Example**

In the following example, the result of the AND operation on numeric literals 5 and 3 is returned.

```
SELECT BITAND(5,3) FROM DUAL;
   bitand
-----
           1
(1 row)
```

### F.56.5.1.3. BITOR

**Description**

Performs a bitwise OR operation.

**Syntax**

```
BITOR(int1 bigint, int2 bigint) returns bigint
```

**General rules**

- BITOR performs an OR operation on each bit of two bigint, and returns the result.
- Specify bigint type values.
- The data type of the return value is BIGINT.

**Note**

- If using BITOR, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

In the following example, the result of the OR operation on numeric literals 5 and 3 is returned.

```
SELECT BITOR(5,3) FROM DUAL;  
bitor  
-----  
       7  
(1 row)
```

**F.56.5.1.4. BITXOR****Description**

Performs a bitwise XOR operation.

**Syntax**

```
BITXOR(int1 bigint, int2 bigint) returns bigint
```

**General rules**

- BITXOR performs an XOR operation on each bit of two integers, and returns the result.
- Specify bigint type values.
- The data type of the return value is BIGINT.

**Note**

- If using BITXOR, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using oraofce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

In the following example, the result of the XOR operation on numeric literals 5 and 3 is returned.

```
SELECT BITXOR(5,3) FROM DUAL;
  bitxor
-----
         6
(1 row)
```

**F.56.5.1.5. COSH**

**Description**

Calculates the hyperbolic cosine of a number.

**Syntax**

```
COSH(num numeric) returns double precision
```

**General rules**

- COSH returns the hyperbolic cosine of the specified number.
- The number must be a numeric data type.
- The data type of the return value is DOUBLE PRECISION.

**Example**

In the following example, the hyperbolic cosine of the numeric literal 2.236 is returned.

```
SELECT COSH(2.236) FROM DUAL;
      cosh
-----
4.7313591000247
(1 row)
```

**F.56.5.1.6. MOD**

**Description**

MOD returns the remainder of n2 divided by n1. Returns n2 if n1 is 0.

**Syntax**

```
MOD(n2 bigint, n1 bigint) returns bigint
MOD(n2 integer, n1 integer) returns integer
MOD(n2 numeric, n1 numeric) returns numeric
MOD(n2 smallint, n1 smallint) returns smallint
```

**General rules**

- This function takes as arguments any numeric datatype.

**Note**

- It is not supported yet if one of the arguments is decimal number in string form and the other is an integer.

**Example**

```
SELECT mod(5,2) FROM DUAL;
mod
-----
1
```

**F.56.5.1.7. REMAINDER****Description**

Returns the remainder of n2 divided by n1.

**Syntax**

```
REMAINDER(n2 numeric, n1 numeric) returns numeric
```

**General rules**

- This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type.
- The MOD function is similar to REMAINDER except that it uses FLOOR in its formula, whereas REMAINDER uses ROUND.
- If  $n1 \neq 0$ , then the remainder is  $n2 - (n1 * N)$  where N is the integer nearest  $n2/n1$ . If  $n2/n1$  equals  $x.5$ , then N is the nearest even integer.

**Note**

- If using REMAINDER, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
SELECT REMAINDER(5.5,2) FROM DUAL;
remainder
-----
-0.5
(1 row)
```

### F.56.5.1.8. ROUND\_TIES\_TO\_EVEN

**Description**

The function returns n rounded to integer places.

**Syntax**

```
ROUND_TIES_TO_EVEN(n NUMERIC, integer int4 DEFAULT 0) returns  
numeric
```

**General rules**

- If integer is positive, n is rounded to integer places to the right of the decimal point.
- If integer is not specified, then n is rounded to 0 places.
- If integer is negative, then n is rounded to integer places to the left of the decimal point.

**Note**

- If using ROUND\_TIES\_TO\_EVEN, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

The following example rounds a number to one decimal point to the right:

```
SELECT ROUND_TIES_TO_EVEN(45.177,1) "ROUND_EVEN" FROM DUAL;  
ROUND_EVEN  
-----  
         45.2  
(1 row)
```

The following example rounds a number to one decimal point to the left:

```
SELECT ROUND_TIES_TO_EVEN(45.177,-1) "ROUND_EVEN" FROM DUAL;  
ROUND_EVEN  
-----  
         50  
(1 row)
```

### F.56.5.1.9. SINH

**Description**

Calculates the hyperbolic sine of a number.

**Syntax**

`SINH(num numeric)` returns double precision

**General rules**

- `SINH` returns the hyperbolic sine of the specified number.
- The number must be a numeric data type.
- The data type of the return value is `DOUBLE PRECISION`.

**Example**

In the following example, the hyperbolic sine of the numeric literal 1.414 is returned.

```
SELECT SINH(1.414) FROM DUAL;
      sinh
-----
1.93460168824956
(1 row)
```

**F.56.5.1.10. TANH****Description**

Calculates the hyperbolic tangent of a number.

**Syntax**

`TANH(num numeric)` returns double precision

**General rules**

- `TANH` returns the hyperbolic tangent of the specified number.
- The number must be a numeric data type.
- The data type of the return value is `DOUBLE PRECISION`.

**Example**

In the following example, the hyperbolic tangent of the numeric literal 3 is returned.

```
SELECT TANH(3) FROM DUAL;
      tanh
-----
0.995054753686731
(1 row)
```

**F.56.5.1.11. CEIL****Description**

Returns the smallest integer(type interval will extract the days to number first) that is greater than or equal to a number.

**Syntax**

```
CEIL(i interval) returns number
CEIL(n numeric) returns numeric
CEIL(d double precision) returns numeric
```

**General rules**

- CEIL returns the smallest integer that is greater than or equal to a number.
- The number may be an interval type or numeric data type or double precision type.
- The data type of the return value is number or numeric.

**Example**

In the following example, returns the smallest integer that is greater than or equal to that number. If the argument is of type interval, extract days from an interval first which is of type numeric, and then returns the smallest integer that is greater than or equal to that number

```
select ceil(sysdate - '2023-01-01'::date) FROM dual ;
  ceil
-----
    335
(1 row)

select ceil(sysdate - to_date('2023-11-27','yyyy-mm-dd')) FROM
dual;
  ceil
-----
     5
(1 row)

select ceil(sysdate - to_date('2023-01-01','yyyy-mm-dd')) FROM
dual;
  ceil
-----
    335
(1 row)
```

**F.56.5.2. String Functions**

The following string functions are supported:

- BTRIM
- INSTR
- INSTRB
- LENGTH
- LENGTHB
- LPAD
- LTRIM

- NLSSORT
- REGEXP\_COUNT
- REGEXP\_INSTR
- REGEXP\_LIKE
- REGEXP\_SUBSTR
- REGEXP\_REPLACE
- REPLACE
- RPAD
- RTRIM
- SOUNDEX
- SUBSTR
- SUBSTRB
- CONCAT
- UPPER

#### **F.56.5.2.1. BTRIM**

##### **Description**

Removes the specified characters from the beginning and end of a string.

##### **Syntax**

```
BTRIM(str text) returns text
BTRIM(str text, trimChars text) returns text
BTRIM(str clob) returns clob
BTRIM(str clob, trimChars clob) returns clob
```

##### **General rules**

- BTRIM returns a string with *trimChars* removed from the beginning and end of string *str*.
- If multiple trim characters are specified, all characters matching the trim characters are removed. If *trimChars* is omitted, all leading and trailing halfwidth spaces are removed.
- The data type of the return value is TEXT if the first parameter is of `text` data type, CLOB if the first parameter is of `clob` data type.

##### **Note**

- BTRIM does not exist for Oracle databases.
- The CHAR type specification for BTRIM uses orafce for its behavior, which is different to that of BTRIM of LightDB. The `search_path` parameter must be modified for it to behave the same as the specification described above.

##### **Information**

The general rule for BTRIM of LightDB is as follows:

- If the string is CHAR type, trailing spaces are removed and then the trim characters are removed.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "The SQL Language" > "Functions and Operators" > "String Functions and Operators" in the LightDB Documentation for information on BTRIM.

**Example**

In the following example, a string that has had "a" removed from both ends of "aabcaba" is returned.

```
SELECT BTRIM('aabcaba', 'a') FROM DUAL;
 btrim
-----
  bcab
(1 row)
```

### F.56.5.2.2. INSTR

**Description**

Returns the position of a substring in a string.

**Syntax**

```
INSTR(str1 text, str2 text) returns integer
INSTR(str1 text, str2 text, startPos integer) returns integer
INSTR(str1 text, str2 text, startPos integer, occurrences
integer) returns integer
```

**General rules**

- INSTR searches for substring *str2* in string *str1* and returns the position (in characters) in *str1* of the first character of the occurrence.
- The search starts from the specified start position *startPos* in *str1*.
- When *startPos* is 0 or negative, the start position will be the specified number of characters from the left of the end of *str1*, and INSTR will search backward from that point.
- If the start position is not specified, the search will be performed from the beginning of *str1*.
- If *occurrences* is specified, the position in *str1* of the nth occurrence of *str2* is returned. Only positive numbers can be specified.
- If *occurrences* is not specified, the start position of the first occurrence that is found is returned.
- If *str2* is not found in *str1*, 0 is returned.
- For *startPos* and *occurrences*, specify a SMALLINT or INTEGER type.
- The data type of the return value is INTEGER.

**Example**

In the following example, characters "BC" are found in string "ABCACBCAAC", and the position of those characters is returned.

```
SELECT INSTR('ABCACBCAAC', 'BC') FROM DUAL;
instr
-----
      2
(1 row)

SELECT INSTR('ABCACBCAAC', 'BC', -1, 2) FROM DUAL;
instr
-----
      2
(1 row)
```

### F.56.5.2.3. INSTRB

#### Description

The INSTRB function searches a string for a substring using bytes and returns the position in the string that is the first byte of a specified occurrence of the substring.

#### Syntax

```
INSTRB( p_source text, p_search text, p_position int4 default
1, p_occurrence int4 default 1) RETURNS integer
```

#### General rules

- INSTRB searches for substring *p\_search* in string *p\_source* and returns the position (in bytes) in *p\_source* of the first byte of the occurrence.
- The search starts from the specified start position *p\_position* in *p\_source*.
- When *p\_position* is 0 or negative, it will raise an error. It is different from ORACLE, in oracle , *p\_position* will be the specified number of bytes from the left of the end of *p\_source*, and INSTRB will search backward from that point.
- If the start position is not specified, the search will be performed from the beginning of *p\_source*.
- If *p\_occurrence* is specified, the position in *p\_source* of the nth occurrence of *p\_search* is returned. Only positive numbers can be specified.
- If *occurrences* is not specified, the start position of the first occurrence that is found is returned.
- If *p\_search* is not found in *p\_source*, 0 is returned.
- The data type of the return value is integer.

#### Note

- If using INSTRB, it is necessary to specify "oracle" for search\_path in advance.

#### See

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

#### Example

In the following example, characters "on" are found in string "hhh##onhx", and the position of those bytes is returned.

```
SELECT INSTRB('hhh##onhx', 'on') FROM DUAL;
```

```
instrb
-----
      10
(1 row)
```

```
SELECT INSTRB('hhh##onhx on xxxx', 'on', 7, 2) FROM DUAL;
```

```
instrb
-----
      15
(1 row)
```

#### F.56.5.2.4. LENGTH

##### Description

Returns the length of a string in number of characters.

##### Syntax

```
LENGTH(str text) returns integer
```

##### General rules

- LENGTH returns the number of characters in string *str*.
- If the string is CHAR type, trailing spaces are included in the length.
- The data type of the return value is INTEGER.

##### Note

The LENGTH specification above uses orafce for its behavior, which is different to that of LENGTH of LightDB. The search\_path parameter must be modified for it to behave according to the orafce specification.

##### Information

The general rule for LENGTH of LightDB is as follows:

- If the string is CHAR type, trailing spaces are not included in the length.

##### See

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "The SQL Language" > "Functions and Operators" > "String Functions and Operators" in the LightDB Documentation for information on LENGTH.

##### Example

In the following example, the number of characters in column col2 (defined using CHAR(10)) in table t1 is returned.

```

SELECT col2,LENGTH(col2) FROM t1 WHERE col1 = '1001';
   col2      | length
-----+-----
AAAAA       |      10
(1 row)

```

### F.56.5.2.5. LENGTHB

#### Description

Returns the length of a string in number of bytes.

#### Syntax

`LENGTHB(str text)` returns integer

#### General rules

- `LENGTHB` returns the number of bytes in string *str*.
- If the string is `CHAR` type, trailing spaces are included in the length.
- The data type of the return value is `INTEGER`.

#### Example

In the following example, the number of bytes in column `col2` (defined using `CHAR(10)`) in table `t1` is returned. Note that, in the second `SELECT` statement, each character in "\*" has a length of 3 bytes, for a total of 9 bytes, and 7 bytes are added for the 7 trailing spaces. This gives a result of 16 bytes.

```

SELECT col2,LENGTHB(col2) FROM t1 WHERE col1 = '1001';
   col2      | lengthb
-----+-----
AAAAA       |      10
(1 row)

SELECT col2,LENGTHB(col2) FROM t1 WHERE col1 = '1004';
   col2      | lengthb
-----+-----
***         |      16
(1 row)

```

### F.56.5.2.6. LPAD

#### Description

Left-pads a string to a specified length with a sequence of characters.

#### Syntax

```

LPAD(str text, len integer) returns text
LPAD(str text, len integer, paddingStr text) returns text
LPAD(str CLOB, len integer, str text) returns clob

```

**General rules**

- LPAD returns the result after repeatedly padding the beginning of string *str* with padding characters *paddingStr* until the string reaches length *len*.
- If the string is CHAR type, the padding characters are added to the string without removing trailing spaces.
- In the resultant string, fullwidth characters are recognized as having a length of 2, and halfwidth characters having a length of 1. If a fullwidth character cannot be included in the resultant string because there is only space available for one halfwidth character, the string is padded with a single-byte space.
- The data type of the return value is TEXT if the first parameter is of `text` data type, CLOB if the first parameter is of `clob` data type.

**Note**

The LPAD specification above uses orafce for its behavior, which is different to that of LPAD of LightDB. The search\_path parameter must be modified for it to behave according to the orafce specification.

**Information**

The general rules for LPAD of LightDB are as follows:

- If the string is CHAR type, trailing spaces are removed and then the padding characters are added to the string.
- The result length is the number of characters.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "The SQL Language" > "Functions and Operators" > "String Functions and Operators" in the LightDB Documentation for information on LPAD.

**Example**

In the following example, a 10-character string that has been formed by left-padding the string "abc" with "a" is returned.

```
SELECT LPAD('abc',10,'a') FROM DUAL;
      lpad
-----
aaaaaaaabc
(1 row)
```

**F.56.5.2.7. LTRIM****Description**

Removes the specified characters from the beginning of a string.

**Syntax**

```
LTRIM(str text) returns text
LTRIM(str text, trimChars text) returns text
```

```
LTRIM(str clob) returns clob
LTRIM(str clob, trimChars clob) returns clob
```

### General rules

- LTRIM returns a string with *trimChars* removed from the beginning of string *str*.
- If multiple trim characters are specified, all characters matching the trim characters are removed. If *trimChars* is omitted, all leading halfwidth spaces are removed.
- The data type of the return value is TEXT if the first parameter is of `text` data type, CLOB if the first parameter is of `clob` data type.

### Note

The LTRIM specification above uses orafce for its behavior, which is different to that of LTRIM of LightDB. The `search_path` parameter must be modified for it to behave according to the orafce specification.

### Information

The general rules for LTRIM of LightDB are as follows:

- If the string is CHAR type, trailing spaces are removed and then the trim characters are removed.

### See

- Refer to "Notes on Using orafce" for information on how to edit `search_path`.
- Refer to "The SQL Language" > "Functions and Operators" > "String Functions and Operators" in the LightDB Documentation for information on LTRIM.

### Example

In the following example, a string that has had "ab" removed from the beginning of "aabcab" is returned.

```
SELECT LTRIM('aabcab','ab') FROM DUAL;
 ltrim
-----
  cab
(1 row)
```

## F.56.5.2.8. NLSSORT

### Description

Returns a byte string that denotes the lexical order of the locale (COLLATE).

### Syntax

```
NLSSORT(str text) returns bytea
NLSSORT(str text, locale text) returns bytea
```

### General rules

- NLSSORT is used for comparing and sorting in the collating sequence of a locale (COLLATE) that differs from the default locale.

- Values that can be specified for the locale differ according to the operating system of the database server.
- If the locale is omitted, it is necessary to use `set_nls_sort` to set the locale in advance. To set the locale using `set_nls_sort`, execute a `SELECT` statement.
- The data type of the return value is `BYTEA`.

**Example of setting `set_nls_sort` using a `SELECT` statement**

```
SELECT set_nls_sort('en_US.UTF8');
```

**Note**

If specifying locale encoding, ensure it matches the database encoding.

**See**

Refer to "Server Administration" > "Localization" > "Locale Support" in the LightDB Documentation for information on the locales that can be specified.

**Example**

**Table F.111. Composition of table (t3)**

col1	col2
1001	aabcababc
2001	abcdef
3001	aacbaab

In the following example, the result of sorting column `col2` in table `t3` by "`da_DK.UTF8`" is returned.

```
SELECT col1,col2 FROM t3 ORDER BY NLSSORT(col2,'da_DK.UTF8');
col1 | col2
-----+-----
2001 | abcdef
1001 | aabcababc
3001 | aacbaab
(3 row)
```

**F.56.5.2.9. REGEXP\_COUNT**

**Description**

Searches a string for a regular expression, and returns a count of the matches.

**Syntax**

```
REGEXP_COUNT(string text, pattern text) returns integer
REGEXP_COUNT(string text, pattern text, startPos integer)
returns integer
REGEXP_COUNT(string text, pattern text, startPos integer,
flags text) returns integer
```

**General rules**

- REGEXP\_COUNT returns the number of times *pattern* occurs in a source *string*. It returns an integer indicating the number of occurrences of *pattern*. If no match is found, then the function returns 0. Returns NULL if one of the parameters is NULL, but the 'flags' parameter could be NULL.
- The search starts from the specified start position *startPos* in *string*, default starts from the beginning of *string*.
- *startPos* is a positive integer, negative values to search from the end of *string* are not allowed.
- *flags* is a character expression that lets you change the default matching behavior of the function.

**The value of *flags* can include one or more of the following characters:**

- 'i': case-insensitive matching.
- 'c': case-sensitive and accent-sensitive matching.
- 'n': the period (.) match the newline character. By default the period does not match the newline character.
- 'm': treats the source string as multiple lines.
- 'x': ignores whitespace characters. By default, whitespace characters match themselves.

**If you omit *flags* then:**

- The default is case and accent sensitivity.
- A period (.) does not match the newline character.
- The source string is treated as a single line.

**Note**

If using the REGEXP\_COUNT function, it is necessary to specify "oracle" for search\_path in advance.

**See**

Refer to "Notes on Using Oracle" for information on how to edit search\_path.

**Example**

```
SELECT REGEXP_COUNT('a' || CHR(10) || 'd', 'a.d') FROM DUAL;
  regexp_count
-----
              0
(1 row)

SELECT REGEXP_COUNT('a' || CHR(10) || 'd', 'a.d', 1, 'm') FROM
DUAL;
  regexp_count
-----
              0
(1 row)

SELECT REGEXP_COUNT('a' || CHR(10) || 'd', 'a.d', 1, 'n') FROM
DUAL;
  regexp_count
```

```

-----
              1
(1 row)

SELECT REGEXP_COUNT('a'||CHR(10)||'d', '^d$', 1, 'm') FROM
DUAL;
  regexp_count
-----
              1
(1 row)

```

### F.56.5.2.10. REGEXP\_INSTR

#### Description

Returns the beginning or ending position within the string where the match for a pattern was located.

#### Syntax

```

REGEXP_INSTR(string text, pattern text) returns integer
REGEXP_INSTR(string text, pattern text, startPos integer)
returns integer
REGEXP_INSTR(string text, pattern text, startPos integer,
occurrence integer) returns integer
REGEXP_INSTR(string text, pattern text, startPos integer,
occurrence integer) returns integer
REGEXP_INSTR(string text, pattern text, startPos integer,
occurrence integer, return_opt integer) returns integer
REGEXP_INSTR(string text, pattern text, startPos integer,
occurrence integer, return_opt integer, flags text) returns
integer
REGEXP_INSTR(string text, pattern text, startPos integer,
occurrence integer, return_opt integer, flags text) returns
integer
REGEXP_INSTR(string text, pattern text, startPos integer,
occurrence integer, return_opt integer, flags text, group integer)
returns integer

```

#### General rules

- REGEXP\_INSTR returns an integer indicating the beginning or ending position of the matched substring, depending on the value of the *return\_opt* argument. If no match is found, then the function returns 0.
- The search starts from the specified start position *startPos* in *string*, default starts from the beginning of *string*.
- *startPos* is a positive integer, negative values to search from the end of *string* are not allowed.
- *occurrence* is a positive integer indicating which occurrence of *pattern* in *string* should be search for. The default is 1, meaning the first occurrence of *pattern* in *string*.
- *return\_opt* lets you specify what should be returned in relation to the occurrence:
  - return\_opt = 0, the position of the first character of the occurrence is returned. This is the default.
  - return\_opt = 1, the position of the character following the occurrence is returned.

- *flags* is a character expression that lets you change the default matching behavior of the function. See REGEXP\_COUNT for detailed information.
- For a *pattern* with capture group, *group* is a positive integer indicating which capture group in *pattern* shall be returned by the function. Capture groups can be nested, they are numbered in order in which their left parentheses appear in *pattern*. If *group* is zero, then the position of the entire substring that matches the pattern is returned. If *group* value exceed the number of capture groups in *pattern*, the function returns zero. A null *group* value returns *NULL*. The default value for *group* is zero.

**Note**

If using the REGEXP\_INSTR function, it is necessary to specify "oracle" for search\_path in advance.

**See**

Refer to "Notes on Using oracle" for information on how to edit search\_path.

**Example**

```

SELECT REGEXP_INSTR('1234567890', '(123)(4(56)(78))') FROM
DUAL;
  regexp_instr
  -----
          1
(1 row)

SELECT REGEXP_INSTR('1234567890', '(4(56)(78))', 3) FROM DUAL;
  regexp_instr
  -----
          4
(1 row)

SELECT REGEXP_INSTR('123 123456 1234567, 1234567 1234567 12',
'^ ]+', 1, 6) FROM DUAL;
  regexp_instr
  -----
          37
(1 row)

SELECT REGEXP_INSTR('199 Oretax Prayers, Riffles Stream, CA',
'[S|R|P][[:alpha:]]{6}', 3, 2, 1) FROM DUAL;
  regexp_instr
  -----
          28
(1 row)

```

**F.56.5.2.11. REGEXP\_LIKE**

**Description**

Condition in the WHERE clause of a query, causing the query to return rows that match the given pattern.

**Syntax**

REGEXP\_LIKE(string text, pattern text) returns boolean  
 REGEXP\_LIKE(string text, pattern text, flags text) returns boolean

**General rules**

- REGEXP\_LIKE is similar to the LIKE condition, except it performs regular expression matching instead of the simple pattern matching performed by LIKE.
- Returns a boolean, *true* when *pattern* match in *string*, *false* otherwise. Returns NULL if one of the parameters is NULL, but the 'flags' parameter could be NULL.
- *flags* is a character expression that lets you change the default matching behavior of the function. See REGEXP\_COUNT for detailed information.

**Note**

If using the REGEXP\_LIKE function, it is necessary to specify "oracle" for search\_path in advance.

**See**

Refer to "Notes on Using Oracle" for information on how to edit search\_path.

**Example**

```
SELECT REGEXP_LIKE('a' || CHR(10) || 'd', 'a.d', 'm') FROM DUAL;
regexp_like
-----
f
(1 row)

SELECT REGEXP_LIKE('a' || CHR(10) || 'd', 'a.d', 'n') FROM DUAL;
regexp_like
-----
t
(1 row)
```

**F.56.5.2.12. REGEXP\_SUBSTR**

**Description**

Returns the string that matches the pattern specified in the call to the function.

**Syntax**

REGEXP\_SUBSTR(string text, pattern text) returns text  
 REGEXP\_SUBSTR(string text, pattern text, startPos integer) returns text  
 REGEXP\_SUBSTR(string text, pattern text, startPos integer, occurrence integer) returns text  
 REGEXP\_SUBSTR(string text, pattern text, startPos integer, occurrence integer, flags text) returns text  
 REGEXP\_SUBSTR(string text, pattern text, startPos integer, occurrence integer, flags text, group int) returns text  
 REGEXP\_SUBSTR(string CLOB, pattern text) returns clob

**General rules**

- REGEXP\_SUBSTR returns the matched substring resulting from matching a POSIX regular expression pattern to a string. If no match is found, then the function returns *NULL*. Returns *NULL* if one of the parameters is *NULL*, but the 'flags' parameter could be *NULL*. The function returns the string as TEXT or CLOB data in the same character set as the first argument.
- The search starts from the specified start position *startPos* in *string*, default starts from the beginning of *string*.
- *startPos* is a positive integer, negative values to search from the end of *string* are not allowed.
- *occurrence* is a positive integer indicating which occurrence of *pattern* in *string* should be search for. The default is 1, meaning the first occurrence of *pattern* in *string*.
- *flags* is a character expression that lets you change the default matching behavior of the function. See REGEXP\_COUNT for detailed information.
- For a *pattern* with capture group, *\*group\** is a positive integer indicating which capture group in *pattern* shall be returned by the function. Capture groups can be nested, they are numbered in order in which their left parentheses appear in *pattern*. If *group* is zero, then the position of the entire substring that matches the pattern is returned. If *group* value exceed the number of capture groups in *pattern*, the function returns *NULL*. A null *group* value returns *NULL*. The default value for *group* is zero.

**Note**

If using the REGEXP\_SUBSTR function, it is necessary to specify "oracle" for search\_path in advance.

**See**

Refer to "Notes on Using orafce" for information on how to edit search\_path.

**Example**

```

SELECT REGEXP_SUBSTR('number of your street, zipcode town, FR',
',[^,]+' ) FROM DUAL;
   regexp_substr
-----
, zipcode town
(1 row)

SELECT regexp_substr('number of your street, zipcode town, FR',
',[^,]+', 24) FROM DUAL;
   regexp_substr
-----
, FR
(1 row)

SELECT regexp_substr('number of your street, zipcode town, FR',
',[^,]+', 1, 2) FROM DUAL;
   regexp_substr
-----
, FR
(1 row)

SELECT regexp_substr('1234567890 1234567890', '(123)(4(56)
(78))', 1, 1, 'i', 0) FROM DUAL;

```

```

    regexp_substr
    -----
    12345678
    (1 row)

```

### F.56.5.2.13. REGEXP\_REPLACE

#### Description

Returns the string that matches the pattern specified in the call to the function.

#### Syntax

```

    REGEXP_REPLACE(string text, pattern text, replace_string text,
startPos integer,
    occurrence integer, flags text) returns text
    REGEXP_REPLACE(string clob, pattern text, replace_string text)
returns clob

```

#### General rules

- REGEXP\_REPLACE returns a modified version of the source string where occurrences of a POSIX regular expression pattern found in the source string are replaced with the specified replacement string. If no match is found or the occurrence queried exceed the number of match, then the source string untouched is returned. The function returns TEXT if the first parameter is not a CLOB and returns CLOB if the first parameter is a CLOB.
- The search and replacement starts from the specified start position *startPos* in *string*, default starts from the beginning of *string*.
- *startPos* is a positive integer, negative values to search from the end of *string* are not allowed.
- *occurrence* is a positive integer indicating which occurrence of *pattern* in *string* should be search for and replaced. The default is 0, meaning all occurrences of *pattern* in *string*.
- *flags* is a character expression that lets you change the default matching behavior of the function. See REGEXP\_COUNT for detailed information.

#### Note

If using the REGEXP\_REPLACE function, it is necessary to specify "oracle" for search\_path in advance.

#### See

Refer to "Notes on Using orafce" for information on how to edit search\_path.

#### Example

```

    SELECT regexp_replace('512.123.4567 612.123.4567',
'([[:digit:]]{3})\.[[:digit:]]{3})\.[[:digit:]]{4}'), '(\1) \2-
\3') FROM DUAL;
    regexp_replace
    -----
    (512) 123-4567 (612) 123-4567
    (1 row)

```

```

SELECT oracle.REGEXP_REPLACE('number    your    street,
zipcode town, FR', '( ){2,}', ' ', 9);
           regexp_replace
-----
number    your street, zipcode town, FR
(1 row)

SELECT oracle.REGEXP_REPLACE('number    your    street,
zipcode town, FR', '( ){2,}', ' ', 9, 2);
           regexp_replace
-----
number    your    street, zipcode town, FR
(1 row)

```

### F.56.5.2.14. REPLACE

#### Description

Returns string with every occurrence of search\_string replaced with replacement\_string.

#### Syntax

```

REPLACE(string text, pattern text) returns text
REPLACE(string text, pattern text, replace_string text)
returns text
REPLACE(string uuid, pattern text, replace_string text)
returns text
REPLACE(string CLOB, pattern text) returns CLOB
REPLACE(string CLOB, pattern text, replace_string text)
returns CLOB

```

#### General rules

- If replace\_string is omitted or null, then all occurrences of search\_string are removed. If search\_string is null, then string is returned.
- The function returns TEXT if the first argument is not a CLOB and returns CLOB if the first argument is a CLOB.

#### Note

The above REPLACE specification uses orafce for its behavior, which is different to that of REPLACE of LightDB. The search\_path parameter must be modified for it to behave according to the orafce specification.

#### Information

The general rules for REPLACE of LightDB are as follows:

- If replace\_string or search\_string is null, then null is returned.

#### See

Refer to "Notes on Using orafce" for information on how to edit search\_path.

#### Example

```
SELECT REPLACE('abcdAbcdasd', 'a') FROM DUAL;
      replace
-----
bcdAbcdsd
(1 row)
```

```
SELECT REPLACE('abcdAbcdasd', 'a','c') FROM DUAL;
      replace
-----
cbcdAbcdcsd
(1 row)
```

```
SELECT REPLACE('abcdAbcdasd', NULL,'c') FROM DUAL;
      replace
-----
abcdAbcdasd
(1 row)
```

```
SELECT REPLACE('abcdAbcdasd', 'a',NULL) FROM DUAL;
      replace
-----
bcdAbcdsd
(1 row)
```

### F.56.5.2.15. RPAD

#### Description

Right-pads a string to a specified length with a sequence of characters.

#### Syntax

```
RPAD(str text, len integer) returns text
RPAD(str text, len integer, paddingStr text) returns text
RPAD(str CLOB, len integer, paddingStr text) returns CLOB
```

#### General rules

- RPAD returns the result after repeatedly padding the end of string *str* with padding characters *paddingStr* until the string reaches length *len*.
- If the string is CHAR type, the padding characters are added to the string without removing trailing spaces.
- In the resultant string, fullwidth characters are recognized as having a length of 2, and halfwidth characters having a length of 1. If a fullwidth character cannot be included in the resultant string because there is only space available for one halfwidth character, the string is padded with a single-byte space.
- The string returned is of TEXT data type if the first parameter is a character data type, and a CLOB if the first parameter is a CLOB data type.

#### Note

The RPAD specification above uses `orafce` for its behavior, which is different to that of RPAD of `LightDB`. The `search_path` parameter must be modified for it to behave according to the `orafce` specification.

**Information**

The general rules for RPAD of LightDB are as follows:

- If the string is CHAR type, trailing spaces are removed and then the padding characters are added to the string.
- The result length is the number of characters.

**See**

- Refer to "Notes on Using oraAce" for information on how to edit search\_path.
- Refer to "The SQL Language" > "Functions and Operators" > "String Functions and Operators" in the LightDB Documentation for information on RPAD.

**Example**

In the following example, a 10-character string that has been formed by right-padding the string "abc" with "a" is returned.

```
SELECT RPAD( 'abc' ,10 , 'a' ) FROM DUAL;
      rpad
-----
abcaaaaaaa
(1 row)
```

**F.56.5.2.16. RTRIM****Description**

Removes the specified characters from the end of a string.

**Syntax**

```
RTRIM(str text) returns text
RTRIM(str text, trimChars text) returns text
RTRIM(str clob) returns clob
RTRIM(str clob, trimChars text) returns clob
```

**General rules**

- RTRIM returns a string with *trimChars* removed from the end of string *str*.
- If multiple trim characters are specified, all characters matching the trim characters are removed. If *trimChars* is omitted, all trailing halfwidth spaces are removed.
- The string returned is of TEXT data type if the first parameter is a character data type, and a CLOB if the first parameter is a CLOB data type.

**Note**

The RTRIM specification above uses oraAce for its behavior, which is different to that of RTRIM of LightDB. The search\_path parameter must be modified for it to behave the same as the oraAce specification.

**Information**

The general rules for RTRIM of LightDB are as follows:

- If the string is CHAR type, trailing spaces are removed and then the trim characters are removed.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "The SQL Language" > "Functions and Operators" > "String Functions and Operators" in the LightDB Documentation for information on RTRIM.

**Example**

In the following example, a string that has had "ab" removed from the end of "aabcab" is returned.

```
SELECT RTRIM('aabcab', 'ab') FROM DUAL;
 rtrim
-----
 aabc
(1 row)
```

### F.56.5.2.17. SOUNDEX

**Description**

SOUNDEX returns a character string containing the phonetic representation of char. This function lets you compare words that are spelled differently, but sound alike in English.

**Syntax**

```
SOUNDEX(str text) returns text
```

**General rules**

- The phonetic representation is defined in The Art of Computer Programming, Volume 3: Sorting and Searching, by Donald E. Knuth.
- Retain the first letter of the string and remove all other occurrences of the following letters: a, e, h, i, o, u, w, y.
- Assign numbers to the remaining letters as follows:

```
b, f, p, v = 1
c, g, j, k, q, s, x, z = 2
d, t = 3
l = 4
m, n = 5
r = 6
```

- If two or more letters with the same number were adjacent in the original name (before step 1), or adjacent except for any intervening h and w, then retain the first letter and omit rest of all the adjacent letters with same number.
- Return the first four bytes padded with 0.

**Note**

If using the SOUNDEX function, it is necessary to specify "oracle" for search\_path in advance.

**See**

Refer to "Notes on Using oraofce" for information on how to edit search\_path.

**Example**

In the following example, a string that has had "ab" removed from the end of "aabcab" is returned.

```
SELECT SOUNDEX('SMYTHE')=SOUNDEX('Smith') as same FROM DUAL;
same
-----
t
(1 row)
```

**F.56.5.2.18. SUBSTR****Description**

Extracts part of a string using characters to specify position and length.

**Syntax**

```
SUBSTR(str text, startPos integer) returns text
SUBSTR(str text, startPos numeric) returns text
SUBSTR(str text, startPos integer, len integer) returns text
SUBSTR(str text, startPos numeric, len numeric) returns text
SUBSTR(str CLOB, startPos number) returns CLOB
SUBSTR(str CLOB, startPos number, len number) returns CLOB
```

**General rules**

- SUBSTR extracts and returns a substring of string *str*, beginning at position *startPos*, for number of characters *len*.
- When *startPos* is positive, it will be the number of characters from the beginning of the string.
- When *startPos* is 0, it will be treated as 1.
- When *startPos* is negative, it will be the number of characters from the end of the string.
- When *len* is not specified, all characters to the end of the string are returned. NULL is returned when *len* is less than 1.
- For *startPos* and *len*, specify an integer or NUMERIC type. If numbers including decimal places are specified, they are truncated to integers.
- The string returned is of TEXT data type if the first parameter is a character data type, and a CLOB if the first parameter is a CLOB data type.

**Note**

- There are two types of SUBSTR. One that behaves as described above and one that behaves the same as SUBSTRING. The search\_path parameter must be modified for it to behave the same as the specification described above.
- If the change has not been implemented, SUBSTR is the same as SUBSTRING.

**Information**

The general rules for SUBSTRING of LightDB are as follows:

- The start position will be from the beginning of the string, whether the start position is positive, 0, or negative.
- When *len* is not specified, all characters to the end of the string are returned.
- An empty string is returned if no string is extracted or *len* is less than 1.

**See**

- Refer to "The SQL Language" > "Functions and Operators" > "String Functions and Operators" in the LightDB Documentation for information on SUBSTRING.

**Example**

In the following example, part of the string "ABCDEFGH" is extracted.

```
SELECT SUBSTR('ABCDEFGH',3,4) "Substring" FROM DUAL;
Substring
-----
CDEF
(1 row)
```

```
SELECT SUBSTR('ABCDEFGH',-5,4) "Substring" FROM DUAL;
Substring
-----
CDEF
(1 row)
```

### F.56.5.2.19. SUBSTRB

**Description**

Extracts part of a string using bytes to specify position and length.

**Syntax**

```
SUBSTRB(str text, startPos integer) returns varchar2
SUBSTRB(str text, startPos integer, len integer) returns
varchar2
```

**General rules**

- SUBSTR extracts and returns a substring of string *str*, beginning at byte position *startPos*, for number of byte *len*.
- When *startPos* is 0 or negative, extraction starts at the position found by subtracting 1 from the start position and shifting by that number of positions to the left.
- When *len* is not specified, all bytes to the end of the string are returned.
- An empty string is returned if no string is extracted or *len* is less than 1.
- For *startPos* and *len*, specify a SMALLINT or INTEGER type.
- The data type of the return value is VARCHAR2.

**Note**

The external specification of SUBSTRB is different to that of SUBSTR added by oraace, conforming with SUBSTRING of LightDB.

**Example**

In the following example, part of the string "aaabbbccc" is extracted.

```
SELECT SUBSTRB('aaabbbccc',4,3) FROM DUAL;
 substrb
-----
    bbb
(1 row)

SELECT SUBSTRB('aaabbbccc',-2,6) FROM DUAL;
 substrb
-----
    aaa
(1 row)
```

**F.56.5.2.20. CONCAT****Description**

concatenate two strings

**Syntax**

```
CONCAT(str1 TEXT, str2 TEXT) returns TEXT
CONCAST(str1 CLOB, str2 CLOB) returns CLOB
```

**General rules**

- In concatenations of two different data types, the function returns the data type that results in a lossless conversion.
- This function is equivalent to the concatenation operator (||).
- The string returned is of TEXT data type if the first parameter is a character data type, and a CLOB if the first parameter is a CLOB data type.

**Example**

```
SELECT concat('a', 'b') FROM DUAL;
 concat
-----
    ab
(1 row)

SELECT concat(to_clob('a'), 'b') FROM DUAL;
 concat
-----
    ab
(1 row)
```

### F.56.5.2.21. UPPER

#### Description

UPPER returns string with all letters uppercase.

#### Syntax

```
UPPER(string TEXT) returns TEXT
UPPER(string CLOB) returns CLOB
```

#### General rules

- The string returned is of TEXT data type if the first parameter is a character data type, and a CLOB if the first parameter is a CLOB data type.

#### Example

```
SELECT UPPER('hello world') FROM DUAL;
      upper
-----
HELLO WORLD
(1 row)

SELECT UPPER(to_clob('hello world')) FROM DUAL;
      upper
-----
HELLO WORLD
(1 row)
```

### F.56.5.3. Date/Time Functions

The following date/time functions are supported:

- ADD\_MONTHS
- DBTIMEZONE
- LAST\_DAY
- MONTHS\_BETWEEN
- NEXT\_DAY
- ROUND
- SESSIONTIMEZONE
- SYSDATE
- TRUNC
- TZ\_OFFSET

#### Note

If the DATE type only is shown in the date/time functions, these functions can be used in both Oracle and LightDB.

### F.56.5.3.1. ADD\_MONTHS

#### Description

Adds months to a date.

#### Syntax

```
ADD_MONTHS(date DATE, months INTEGER) returns DATE
ADD_MONTHS(date TIMESTAMP WITH TIME ZONE, months INTEGER)
returns TIMESTAMP
```

#### General rules

- ADD\_MONTHS returns *date plus months*.
- For *date*, specify a DATE or TIMESTAMP WITH TIME ZONE type.
- For *months*, specify a SMALLINT or INTEGER type.
- If a negative value is specified for *months*, the number of months is subtracted from the date.
- The data type of the return value is DATE or TIMESTAMP.

#### Note

If using the DATE type of ora<sub>fc</sub>e, it is necessary to specify "oracle" for search\_path in advance.

#### See

Refer to "Notes on Using ora<sub>fc</sub>e" for information on how to edit search\_path.

#### Example

The example below shows the result of adding 3 months to the date May 1, 2016.

```
SELECT ADD_MONTHS( DATE '2016/05/01', 3 ) FROM DUAL;
      add_months
-----
2016-08-01 00:00:00
(1 row)
```

### F.56.5.3.2. DBTIMEZONE

#### Description

Returns the value of the database time zone.

#### Syntax

```
DBTIMEZONE() returns text
```

#### General rules

- DBTIMEZONE returns the time zone value of the database.
- The data type of the return value is TEXT.

**Note**

- If using DBTIMEZONE, it is necessary to specify "oracle" for search\_path in advance.
- The time zone of the database is set to "GMT" by default. To change the time zone, change the "orafce.timezone" parameter. An example using the SET statement is shown below.

```
SET orafce.timezone = 'Japan';
```

- The orafce.timezone settings can be set using any of the methods for setting server parameters.
- If the SQL statement is executed with orafce.timezone set, the following message may be displayed, however, the parameter settings are enabled, so you can ignore this.

```
WARNING: unrecognized configuration parameter
"orafce.timezone"
```

- The time zones that can be set in "orafce.timezone" are the same as for the "TimeZone" server parameter.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "The SQL Language" > "Data Types" > "Date/Time Types" in the LightDB Documentation for information on the time zone.

**Example**

In the following example, the DBTIMEZONE result is returned.

```
SELECT DBTIMEZONE() FROM DUAL;
dbtimezone
-----
GMT
(1 row)
```

**F.56.5.3.3. LAST\_DAY****Description**

Returns the last day of the month in which the specified date falls.

**Syntax**

```
LAST_DAY(date DATE) returns DATE
LAST_DAY(date TIMESTAMPTZ) returns TIMESTAMPTZ
```

**General rules**

- LAST\_DAY returns the last day of the month in which the specified date falls.
- For *date*, specify a DATE or TIMESTAMPTZ type.

- The data type of the return value is DATE or TIMESTAMPTZ.

**Note**

If using the DATE type of ora<sub>fc</sub>e, it is necessary to specify "oracle" for search\_path in advance.

**See**

Refer to "Notes on Using ora<sub>fc</sub>e" for information on how to edit search\_path.

**Example**

In the example below, the last date of "February 01, 2016" is returned.

```
SELECT LAST_DAY( DATE '2016/02/01' ) FROM DUAL;
      last_day
-----
2016-02-29 00:00:00
(1 row)
```

### F.56.5.3.4. MONTHS\_BETWEEN

**Description**

Returns the number of months between two dates.

**Syntax**

```
MONTHS_BETWEEN(date1 DATE, date2 DATE) returns NUMERIC
MONTHS_BETWEEN(date1 TIMESTAMP WITH TIME ZONE, date2 TIMESTAMP
WITH TIME ZONE) returns NUMERIC
```

**General rules**

- MONTHS\_BETWEEN returns the difference in the number of months between *date1* and *date2*.
- For *date1* and *date2*, specify a DATE or TIMESTAMPTZ type.
- If *date2* is earlier than *date1*, the return value will be negative.
- If two dates fall on the same day, or each of the two dates are the last day of the month to which they belong, an integer is returned. If the days are different, one month is considered to be 31 days, and a value with the difference in the number of days divided by 31 added is returned.
- The data type of the return value is DATE or NUMERIC.

**Note**

If using the DATE type of ora<sub>fc</sub>e, it is necessary to specify "oracle" for search\_path in advance.

**See**

Refer to "Notes on Using ora<sub>fc</sub>e" for information on how to edit search\_path.

**Example**

In the following example, the difference between the months of March 15, 2016 and November 15, 2015 is returned.

```

SELECT MONTHS_BETWEEN(DATE '2016/03/15', DATE '2015/11/15') FROM
DUAL;
      months_between
      -----
              4
(1 row)

```

### F.56.5.3.5. NEXT\_DAY

#### Description

Returns the date of the first instance of a particular day of the week that follows the specified date.

#### Syntax

```

NEXT_DAY(date DATE, dayOfWk TEXT) returns DATE
NEXT_DAY(date DATE, dayOfWk INTEGER) returns DATE
NEXT_DAY(date TIMESTAMP WITH TIME ZONE, dayOfWk TEXT) returns
TIMESTAMP
NEXT_DAY(date TIMESTAMP WITH TIME ZONE, dayOfWk INTEGER)
returns TIMESTAMP

```

#### General rules

- NEXT\_DAY returns the date matching the first instance of *dayOfWk* that follows *date*.
- For *date*, specify a DATE or TIMESTAMPTZ WITH TIME ZONE type.
- Specify a numeric value or string indicating the day of the week.

#### Values that can be specified for the day

**Table F.112. Setting dayOfWk for NEXT\_DAY Function**

Setting example	Overview
1	1 (Sunday) to 7 (Saturday) can be specified
'Sun', or 'Sunday'	English display of the day
'*'	Japanese display of the day

- The data type of the return value is DATE or TIMESTAMP.

#### Note

- If using the DATE type of ora<sub>fc</sub>e, it is necessary to specify "oracle" for search\_path in advance.
- The ability to use Japanese for entering days is provided by the ora<sub>fc</sub>e proprietary specification. Japanese cannot be used for entering days when using date/time functions other than NEXT\_DAY (such as TO\_DATE).

#### See

Refer to "Notes on Using ora<sub>fc</sub>e" for information on how to edit search\_path.

#### Example

In the example below, the date of the first Friday on or after "May 1, 2016" is returned.

```

SELECT NEXT_DAY(DATE'2016/05/01', 'Friday') FROM DUAL;
      next_day
-----
2016-05-06 00:00:00
(1 row)

```

### F.56.5.3.6. ROUND

#### Description

Rounds a date.

#### Syntax

```

ROUND(date DATE) returns DATE
ROUND(date DATE, fmt TEXT) returns DATE
ROUND(date TIMESTAMP WITH TIME ZONE) returns TIMESTAMP WITH
TIME ZONE
ROUND(date TIMESTAMP WITH TIME ZONE, fmt TEXT) returns
TIMESTAMP WITH TIME ZONE
ROUND(date TIMESTAMP WITHOUT TIME ZONE) returns TIMESTAMP
WITHOUT TIME ZONE
ROUND(date TIMESTAMP WITHOUT TIME ZONE, fmt TEXT) returns
TIMESTAMP WITHOUT TIME ZONE

```

#### General rules

- ROUND returns a date rounded to the unit specified by format model *fmt*.
- For *date*, specify a DATE or TIMESTAMPTZ type.
- Specify the format model as a string.

#### Values that can be specified for the format model

**Table F.113. Setting Format Model for ROUND Function**

Format model	Rounding unit
Y,YY,YYY,YYYY, SYYYY, YEAR,SYEAR	Year
I,IY,IYY,IYYY	Year (values including calendar weeks, in compliance with the ISO standard)
Q	Quarter
WW	Week (first day of the year)
IW	Week (Monday of that week)
W	Week (first weekday on which the first day of the month falls)
DAY,DY,D	Week (Sunday of that week)
MONTH,MON,MM,RM	Month
CC,SCC	Century
DDD,DD,J	Day

Format model	Rounding unit
HH,HH12,HH24	Hour
MI	Minute

- If decimal places are rounded: for year, the boundary for rounding is July 1; for month, the day is 16; and for week, the weekday is Thursday.
- If *fmt* is omitted, the date is rounded by day.
- If the DATE type of LightDB is specified for the date, that DATE type will be the data type of the return value. If the TIMESTAMP type is specified for the date, the data type will be TIMESTAMP WITH TIME ZONE, irrespective of whether a time zone is used.

**Example**

In the example below, the result of "June 20, 2016 18:00:00" rounded by Sunday of the week is returned.

```
SELECT ROUND(TIMESTAMP '2016/06/20 18:00:00', 'DAY') FROM DUAL;
           round
-----
2016-06-19 00:00:00+09
(1 row)
```

**F.56.5.3.7. SESSIONTIMEZONE**

**Description**

Returns the time zone of the session.

**Syntax**

```
SESSIONTIMEZONE() returns text
```

**General rules**

- SESSIONTIMEZONE returns the time zone value between sessions.
- The data type of the return value is TEXT.

**Note**

- If using SESSIONTIMEZONE, it is necessary to specify "oracle" for search\_path in advance.
- The value returned by SESSIONTIMEZONE becomes the value set in the "TimeZone" server parameter.

**See**

Refer to "Notes on Using orafce" for information on how to edit search\_path.

**Example**

In the following example, the time zone of the session is returned.

```
SELECT SESSIONTIMEZONE() FROM DUAL;
```

```
sessiontimezone
-----
Japan
(1 row)
```

### F.56.5.3.8. SYSDATE

#### Description

Returns the system date.

#### Syntax

```
SYSDATE() returns oracle.date
```

#### General rules

- SYSDATE returns the system date.
- The data type of the return value is the DATE type of orafce.

#### Note

- If using SYSDATE, it is necessary to specify "oracle" for search\_path in advance.
- The date returned by SYSDATE depends on the time zone value of the orafce database.

#### See

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "DBTIMEZONE" for information on the time zone values of the database.
- Refer to "The SQL Language" > "Data Types" > "Date/Time Types" in the LightDB Documentation for information on the time zone.

#### Example

In the following example, the system date is returned.

```
SELECT SYSDATE() FROM DUAL;
        sysdate
-----
2016-06-22 08:06:51
(1 row)
```

### F.56.5.3.9. TRUNC

#### Description

Truncates a date.

#### Syntax

```
TRUNC(date DATE) returns DATE
TRUNC(date DATE, fmt TEXT) returns DATE
```

TRUNC(date TIMESTAMP WITH TIME ZONE) returns TIMESTAMP WITH TIME ZONE

TRUNC(date TIMESTAMP WITH TIME ZONE, fmt TEXT) returns TIMESTAMP WITH TIME ZONE

TRUNC(date TIMESTAMP WITHOUT TIME ZONE) returns TIMESTAMP WITHOUT TIME ZONE

TRUNC(date TIMESTAMP WITHOUT TIME ZONE, fmt TEXT) returns TIMESTAMP WITHOUT TIME ZONE

### General rules

- TRUNC returns a date truncated to the unit specified by format model *fmt*.
- For *date*, specify a DATE or TIMESTAMP type.
- Specify the format model as a string. The values that can be specified are the same as for ROUND.
- If *fmt* is omitted, the date is truncated by day.
- If the DATE type of LightDB is specified for the date, that DATE type will be the data type of the return value. If the TIMESTAMP type is specified for the date, the data type will be TIMESTAMP WITH TIME ZONE, irrespective of whether a time zone is used.

### See

Refer to "ROUND" for information on the values that can be specified for the format model.

### Example

In the example below, the result of "August 10, 2016 15:30:00" truncated by the day is returned.

```
SELECT TRUNC(TIMESTAMP '2016/08/10 15:30:00', 'DDD') FROM DUAL;
          trunc
-----
2016-08-10 00:00:00+09
(1 row)
```

## F.56.5.3.10. TZ\_OFFSET

### Description

Returns the time zone offset.

### Syntax

TZ\_OFFSET(text) returns text

### General rules

- You can enter a valid time zone region name, a time zone offset from UTC (which simply returns itself).
- For a listing of valid values for time\_zone\_name, query the name column of the pg\_timezone\_names.

### Note

- If using TZ\_OFFSET, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using oraace" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
SELECT TZ_OFFSET('Asia/Shanghai') FROM DUAL;
tz_offset
-----
08:00:00
(1 row)
      (1 row)
```

## F.56.5.4. Data Type Formatting Functions

The following data type formatting functions are supported:

- CONVERT
- NUMTOYMINTERVAL
- TO\_BLOB(raw)
- TO\_CHAR
- TO\_DATE
- TO\_MULTI\_BYTE
- TO\_NUMBER
- TO\_SINGLE\_BYTE
- ASCIISTR
- ASCII
- SQLCODE\_TO\_SQLSTATE
- TO\_CLOB
- RAWTOHEX
- ROWIDTOCHAR

### F.56.5.4.1. CONVERT

**Description**

CONVERT converts a character string from one character set to another.

**Syntax**

```
CONVERT(str TEXT, dest_char_set TEXT, source_char_set TEXT
DEFAULT 'utf8') returns TEXT
```

**General rules**

- The `str` argument is the value to be converted.
- The `dest_char_set` argument is the name of the character set to which `str` is converted.
- The `source_char_set` argument is the name of the character set in which `str` is stored in the database. The default value is the database character set.
- Both the destination and source character set arguments can be either literals or columns containing the name of the character set.
- For complete correspondence in character conversion, it is essential that the destination character set contains a representation of all the characters defined in the source character set. Where a character does not exist in the destination character set, a replacement character appears. Replacement characters can be defined as part of a character set definition.

**Note**

- If using `CONVERT` for converting string, it is necessary to specify "oracle" for `search_path` in advance.

**See**

- Refer to "Notes on Using Oracle" for information on how to edit `search_path`.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
SELECT CONVERT('###', 'gbk', 'utf8') from dual; FROM DUAL;
convert
-----
##
(1 row)
```

**F.56.5.4.2. NUMTOYMINTERVAL****Description**

`NUMTOYMINTERVAL` converts number to an `INTERVAL YEAR TO MONTH` literal.

**Syntax**

```
NUMTOYMINTERVAL(n numeric, interval_unit text) returns
interval
```

**General rules**

- The value for `interval_unit` specifies the unit of `n` and must resolve to one of the following string values: 'YEAR', 'MONTH'.
- `interval_unit` is case insensitive.

**Note**

- If using NUMTOYMINTERVAL for specifying date/time values, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using oraace" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
SELECT NUMTOYMINTERVAL(1, 'YEAR') FROM DUAL;
 numtoyminterval
-----
1 year
(1 row)
```

**F.56.5.4.3. TO\_BLOB(raw)**

**Description**

TO\_BLOB(raw) converts RAW values to BLOB values.

**Syntax**

TO\_BLOB(raw) returns blob

**Note**

- If using the TO\_BLOB(raw) function, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using oraace" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
SELECT TO_BLOB(UTL_RAW.CAST_TO_RAW('##')) FROM DUAL;
 to_blob
-----
\xe6b58be8af95
(1 row)
```

**F.56.5.4.4. TO\_CHAR**

**Description**

Converts a value to a string.

**Syntax**

TO\_CHAR(num SMALLINT) returns TEXT

```
TO_CHAR(num INTEGER) returns TEXT
TO_CHAR(num BIGINT) returns TEXT
TO_CHAR(num REAL) returns TEXT
TO_CHAR(num DOUBLE PRECISION) returns TEXT
TO_CHAR(num NUMERIC) returns TEXT
TO_CHAR(date TIMESTAMP) returns TEXT
TO_CHAR(TEXT) returns TEXT

TO_CHAR(date TIMESTAMP, fmt TEXT) returns TEXT
TO_CHAR(date TIMESTAMP WITH TIME ZONE, fmt TEXT) returns TEXT

TO_CHAR(date TIMESTAMP, fmt TEXT, nls_date_language TEXT)
returns TEXT
TO_CHAR(date TIMESTAMP WITH TIME ZONE, fmt TEXT,
nls_date_language TEXT) returns TEXT
```

### General rules

- TO\_CHAR converts the specified number or date/time value to a string.
- For *num*, specify a numeric data type.
- For *date*, please specify the DATE or TIMESTAMP type. Additionally, you can set the date/time format for the *nls\_date\_format* variable in advance, so you don't need to specify it when calling TO\_CHAR. Here is an example of how to set it using the SET statement.

```
SET nls_date_format = 'YYYY/MM/DD HH24:MI:SS';
```

Whether it is specified at display time or at call time, the format specifier works the same regardless of case.

- For *fmt*, it is used to set the data format. When the first argument is a numeric type, see numeric value formatting functions. When the first argument is a date type, see date value formatting functions.
- For *nls\_date\_language*, it is used to set the display language environment for dates.
- The data type of the return value is TEXT.

### Note

- If using TO\_CHAR for specifying date/time values, it is necessary to specify "oracle" for *search\_path* in advance.
- The *nls\_date\_format* settings can be set using any of the methods for setting server parameters.
- If *nls\_date\_format* is set, the following message may be displayed when an SQL statement is executed, however, the parameter settings are enabled, so you can ignore this.

```
WARNING: unrecognized configuration parameter
"nls_date_format"
```

### See

- Refer to "Notes on Using orafce" for information on how to edit *search\_path*.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

### Example

In the following example, the numeric value "123.45" is returned as a string.

```
SELECT TO_CHAR(123.45) FROM DUAL;
to_char
-----
123.45
(1 row)

SELECT to_char (sysdate, 'YYYY-MM-DD',
'NLS_DATE_LANGUAGE='SIMPLIFIED CHINESE' ');
to_char
-----
2023-12-04
(1 row)
```

### F.56.5.4.5. TO\_DATE

#### Description

Converts a string to a date in accordance with the specified format.

#### Syntax

```
TO_DATE(str TEXT) returns TIMESTAMP
TO_DATE(str TEXT, fmt TEXT) returns TIMESTAMP
```

#### General rules

- TO\_DATE converts string *str* to a date in accordance with the specified format *fmt*.
- Specify a string indicating the date/time.
- Specify the required date/time format. If omitted, the format specified in the `nls_date_format` variable is used. If the `nls_date_format` variable has not been set, the existing date/time input interpretation is used. A setting example using the SET statement is shown below.

```
SET nls_date_format = 'YYYY/MM/DD HH24:MI:SS';
```

- The data type of the return value is `TIMESTAMP`.

#### Note

- The above TO\_DATE specification uses `orafce` for its behavior, which is different to that of TO\_DATE of `LightDB`. The `search_path` parameter must be modified for it to behave according to the `orafce` specification.
- The `nls_date_format` settings can be set using any of the methods for setting server parameters.
- If `nls_date_format` is set, the following message may be displayed when an SQL statement is executed, however, the parameter settings are enabled, so you can ignore this.

```
WARNING: unrecognized configuration parameter
"nls_date_format"
```

**Information**

The general rule for TO\_DATE for specifying the data type format of LightDB is as follows:

- The data type of the return value is the DATE type of LightDB.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "The SQL Language" > "Functions and Operators" > "Data Type Formatting Functions" in the LightDB Documentation for information on TO\_DATE of LightDB.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.
- Refer to "Date/Time Support" > "Date/Time Input Interpretation" in the LightDB Documentation for information on the interpretation of existing date/time input.

**Example**

In the following example, the string "2016/12/31" is converted to a date and returned.

```
SELECT TO_DATE('2016/12/31','YYYY/MM/DD') FROM DUAL;
      to_date
-----
2016-12-31 00:00:00
(1 row)
```

**F.56.5.4.6. TO\_MULTI\_BYTE****Description**

Converts a single-byte string to a multibyte string.

**Syntax**

```
TO_MULTI_BYTE(str TEXT) returns TEXT
```

**General rules**

- TO\_MULTI\_BYTE converts halfwidth characters in string *str* to fullwidth characters, and returns the converted string.
- Specify a string indicating the date/time.
- Specify the required date/time format. If omitted, the format specified in the nls\_date\_format variable is used. If the nls\_date\_format variable has not been set, the existing date/time input interpretation is used. A setting example using the SET statement is shown below.

```
Only halfwidth alphanumeric characters, spaces and symbols
can be converted.
```

- The data type of the return value is TEXT.

**Example**

In the following example, "abc123" is converted to fullwidth characters and returned.

```
SELECT TO_MULTI_BYTE('abc123') FROM DUAL;
to_multi_byte
-----
*****
(1 row)
```

"\*\*\*\*\*" is multibyte "abc123".

#### F.56.5.4.7. TO\_NUMBER

##### Description

Converts a value to a number in accordance with the specified format.

##### Syntax

```
TO_NUMBER(str TEXT) returns NUMERIC
TO_NUMBER(num NUMERIC) returns NUMERIC
TO_NUMBER(num NUMERIC, fmt NUMERIC) returns NUMERIC
```

##### General rules

- TO\_NUMBER converts the specified value to a numeric value in accordance with the specified format *fmt*.
- For *num*, specify a numeric data type.
- For *str*, specify a string indicating the numeric value. Numeric values must comprise only of convertible characters.
- Specify the required numeric data format. The specified numeric value is handled as is as a data type expression.
- The data type of the return value is NUMERIC.

##### See

Refer to "The SQL Language" > "Functions and Operators" > "Data Type Formatting Functions" in the LightDB Documentation for information on numeric value formats.

##### Example

In the following example, the numeric literal "-130.5" is converted to a numeric value and returned.

```
SELECT TO_NUMBER(-130.5) FROM DUAL;
to_number
-----
-130.5
(1 row)
```

#### F.56.5.4.8. TO\_SINGLE\_BYTE

##### Description

Converts a multibyte string to a single-byte string.

**Syntax**

```
TO_SINGLE_BYTE(str TEXT) returns TEXT
```

**General rules**

- TO\_SINGLE\_BYTE converts fullwidth characters in string *str* to halfwidth characters, and returns the converted string.
- Only fullwidth alphanumeric characters, spaces and symbols that can be displayed in halfwidth can be converted.
- The data type of the return value is TEXT.

**Example**

In the following example, "\*\*\*\*\*" is converted to halfwidth characters and returned. "\*\*\*\*\*" is multibyte "xyz999".

```
SELECT TO_SINGLE_BYTE('*****') FROM DUAL;
to_single_byte
-----
xyz999
(1 row)
```

### F.56.5.4.9. ASCIISTR

**Description**

ASCIISTR takes as its argument a string, or an expression that resolves to a string, in any character set and returns an ASCII version of the string in the database character set.

**Syntax**

```
ASCIISTR(str TEXT) returns TEXT
```

**General rules**

- Non-ASCII characters are converted to the form \xxxx, where xxxx represents a UTF-16 code unit.
- The data type of the return value is TEXT.

**Example**

In the following example, "Ä" is converted to "\00C4".

```
SELECT ASCIISTR('ABÄCDE') FROM DUAL;
asciistr
-----
AB\00C4CDE
(1 row)
```

### F.56.5.4.10. ASCII

#### Description

ASCII takes as its argument a string, or an expression that resolves to a string, in any character set and returns an value in the database character set of the first character.

#### Syntax

```
ASCIISTR(str TEXT) returns BIGINT
```

#### General rules

- If your database character set is 7-bit ASCII, then this function returns an ASCII value. If your database character set is UTF-8 Code, then this function returns an UTF-8 value.
- The data type of the return value is BIGINT.

#### Example

In the following example, "Ä" is converted to "50052" in UTF-8.

```
SELECT ORACLE.ASCII('Ä') FROM DUAL;
  ascii
-----
 50052
(1 row)
```

### F.56.5.4.11. SQLCODE\_TO\_SQLSTATE

#### Description

Convert integer error codes to string error codes of length 5.

#### Syntax

```
SQLCODE_TO_SQLSTATE(code INTEGER) returns TEXT
```

#### General rules

- Can only convert integer error codes between 0 and 715827882.
- The data type of the return value is TEXT.

#### Example

In the following example, Conversion error code 2.

```
select SQLCODE_TO_SQLSTATE(2);
  sqlcode_to_sqlstate
-----
 20000
(1 row)
```

### F.56.5.4.12. TO\_CLOB

#### Description

Converts a string or a number to clob.

#### Syntax

```
TO_CLOB(str TEXT) returns CLOB
```

#### General rules

- TO\_CLOB converts the specified value to a clob.

#### Example

```
CREATE TABLE testorafce_to_clob (  
    col_char CHAR(10),  
    col_varchar2 VARCHAR2(20),  
    col_varchar VARCHAR(20),  
    col_nchar NCHAR(10),  
    col_nvarchar2 NVARCHAR2(20),  
    col_smallint smallint,  
    col_integer integer,  
    col_bigint bigint,  
    col_decimal decimal,  
    col_numeric numeric,  
    col_real real,  
    col_double double precision,  
    col_clob CLOB,  
    col_raw raw(10)  
);  
  
INSERT INTO testorafce_to_clob (col_char, col_varchar2,  
    col_varchar, col_nchar, col_nvarchar2, col_smallint, col_integer,  
    col_bigint, col_decimal, col_numeric, col_real, col_double,  
    col_clob, col_raw)  
VALUES ('ABC1', 'Hello', 'World', 'hello', 'world', 1, 2, 3, 4, 5,  
    6, 7, 'This is a CLOB', 'AB');
```

```
INSERT INTO testorafce_to_clob (col_char, col_varchar2,  
    col_varchar, col_nchar, col_nvarchar2, col_smallint, col_integer,  
    col_bigint, col_decimal, col_numeric, col_real, col_double,  
    col_clob, col_raw)  
VALUES ('ABC2', 'Hello', 'World', 'hello', 'world', 1, 2, 3, 4, 5,  
    6, 7, 'This is a CLOB', '1');
```

```
INSERT INTO testorafce_to_clob (col_char, col_varchar2,  
    col_varchar, col_nchar, col_nvarchar2, col_smallint, col_integer,  
    col_bigint, col_decimal, col_numeric, col_real, col_double,  
    col_clob, col_raw)  
VALUES ('ABC3', 'Hello', 'World', 'hello', 'world', 1, 2, 3, 4, 5,  
    6, 7, to_clob('This is a CLOB'), '1AB456789');
```

```
SELECT to_clob(col_char) AS clob_char,  
    to_clob(col_varchar2) AS clob_varchar2,
```

```

to_clob(col_varchar) AS col_varchar,
to_clob(col_nchar) AS clob_nchar,
to_clob(col_nvarchar2) AS clob_nvarchar2,
to_clob(col_clob) AS clob_clob,
to_clob(col_smallint) AS col_smallint,
to_clob(col_integer) AS col_integer,
to_clob(col_bigint) AS col_bigint,
to_clob(col_decimal) AS col_decimal,
to_clob(col_numeric) AS col_numeric,
to_clob(col_real) AS col_real,
to_clob(col_double) AS col_double,
to_clob(col_raw) AS clob_nclob
FROM testorafce_to_clob order by col_char asc;

```

```

clob_char | clob_varchar2 | col_varchar | clob_nchar |
clob_nvarchar2 | clob_clob | col_smallint | col_integer |
col_bigint | col_decimal | col_numeric | col_real | col_double |
clob_nclob
-----+-----+-----+-----
+-----+-----+-----+-----
+-----+-----+-----+-----
+-----
ABC1      | Hello      | world      | hello      | world      |
| This is a CLOB | 1          | 2          | 3          | 4          |
| 5          | 6          | 7          | AB         |            |

| 5          | 6          | 7          | 01AB456789 |            |
(3 rows)

```

### F.56.5.4.13. RAWTOHEX

#### Description

RAWTOHEX CONVERTS THE INCOMING VALUE TO A CHARACTER VALUE THAT CONTAINS ITS HEXADECIMAL REPRESENTATION.

#### Syntax

```

RAWTOHEX(test_raw RAW) returns TEXT
RAWTOHEX(test_text TEXT) returns TEXT
RAWTOHEX(test_uuid UUID) returns VARCHAR2

```

#### General rules

- This function returns a value that has a hexadecimal representation of the bytes that make up the incoming value. Each byte is represented by two hexadecimal numbers.

#### Example

```

select rawtohex(sys_guid());
       rawtohex

```

```
-----  
6466c654a5dc4755902b70d0e6ea6eb6  
(1 row)
```

#### F.56.5.4.14. ROWIDTOCHAR

##### Description

ROWIDTOCHAR CONVERTS THE INCOMING VALUE ROWID of tid type TO a varchar2 type#

##### Syntax

```
ROWIDTOCHAR(test_rowid TID) returns VARCHAR2
```

##### General rules

- This function returns a value that has a varchar2 type,the max length is 18.

##### Example

```
drop TABLE if EXISTS rowidtochar_t1;  
create table rowidtochar_t1  
(  
    id int not null  
);  
insert into rowidtochar_t1 values(1);  
select rowidtochar(rowid) from rowidtochar_t1;  
rowidtochar  
-----  
(0,1)  
(1 row)
```

#### F.56.5.5. Conditional Expressions

The following functions for making comparisons are supported:

- DECODE
- LNNVL
- NANVL
- NVL
- NVL2

##### F.56.5.5.1. DECODE

##### Description

Compares values and if they match, returns a corresponding value.

##### Syntax

```
DECODE(expr, srch, result)
```

```
DECODE(expr, srch, result, default)
DECODE(expr, srch1, result1, srch2, result2)
DECODE(expr, srch1, result1, srch2, result2, default)
DECODE(expr, srch1, result1, srch2, result2, srch3, result3)
DECODE(expr, srch1, result1, srch2, result2, srch3, result3,
default)
```

### General rules

- DECODE compares values of the value expression to be converted and the search values one by one. If the values match, a corresponding result value is returned. If no values match, the default value is returned if it has been specified. A NULL value is returned if a default value has not been specified.
- If the same search value is specified more than once, then the result value returned is the one listed for the first occurrence of the search value.
- The following data types can be used in result values and in the default value:
  - CHAR
  - VARCHAR
  - VARCHAR2
  - NCHAR
  - NCHAR VARYING
  - NVARCHAR2
  - TEXT
  - INTEGER
  - BIGINT
  - NUMERIC
  - DATE
  - TIME WITHOUT TIME ZONE
  - TIMESTAMP WITHOUT TIME ZONE
  - TIMESTAMP WITH TIME ZONE
- The same data type must be specified for the values to be converted and the search values. However, note that different data types may also be specified if a literal is specified in the search value, and the value expression to be converted contains data types that can be converted.
- If the result values and default value are all literals, the data types for these values will be as shown below:
  - If all values are string literals, all will become character types.
  - If there is one or more numeric literal, all will become numeric types.
  - If there is one or more literal cast to the datetime/time types, all will become datetime/time types.
- If the result values and default value contain a mixture of literals and non-literals, the literals will be converted to the data types of the non-literals.

- The same data type must be specified for all result values and for the default value. However, different data types can be specified if the data type of any of the result values or default value can be converted - these data types are listed below:

**Table F.114. Data type combinations that can be converted by DECODE (summary)**

		Other result values or default value		
		Numeric type	Character type	Date/time type
<b>Result value (any)</b>	Numeric type	Y	N	N
	Character type	N	Y	N
	Date/time type	N	N	S(*1)

Y: Can be converted

S: Some data types can be converted

N: Cannot be converted

\*1: The data types that can be converted for date/time types are listed below:

**Table F.115. Result value and default value date/time data types that can be converted by DECODE**

		Other result values or default value			
		DATE	TIME WITHOUT TIME ZONE	TIMESTAMP WITHOUT TIME ZONE	TIMESTAMP WITH TIME ZONE
<b>Result value (any)</b>	DATE	Y	N	Y	Y
	TIME WITHOUT TIME ZONE	N	Y	N	N
	TIMESTAMP WITHOUT TIME ZONE	Y	N	Y	Y
	TIMESTAMP WITH TIME ZONE	Y	N	Y	Y

Y: Can be converted

N: Cannot be converted

- The data type of the return value will be the data type within the result or default value that is longest and has the highest precision.

**Example**

In the following example, the value of col3 in table t1 is compared and converted to a different value. If the col3 value matches search value 1, the result value returned is "one". If the col3 value does not match any of search values 1, 2, or 3, the default value "other number" is returned.

```
SELECT col1,
       DECODE(col3, 1, 'one',
              2, 'two',
```

```

3, 'three',
'other number') "num-word"
FROM t1;
col1 | num-word
-----+-----
1001 | one
1002 | two
1003 | three
(3 rows)

```

### F.56.5.5.2. LNNVL

#### Description

Determines if a value is TRUE or FALSE for the specified condition.

#### Syntax

```
LNNVL(cond BOOLEAN) returns BOOLEAN
```

#### General rules

- LNNVL determines if a value is TRUE or FALSE for the specified condition. If the result of the condition is FALSE or NULL, TRUE is returned. If the result of the condition is TRUE, FALSE is returned.
- The expression for returning TRUE or FALSE is specified in the condition.
- The data type of the return value is BOOLEAN.

#### Example

In the following example, col1 and col3 of table t1 are returned when col3 has a value of 2000 or less, or null values.

```

SELECT col1,col3 FROM t1 WHERE LNNVL( col3 > 2000 );
col1 | col3
-----+-----
1001 | 1000
1002 | 2000
2002 |
(3 row)

```

### F.56.5.5.3. NANVL

#### Description

Returns a substitute value when a value is not a number (NaN).

#### Syntax

```

NANVL(expr FLOAT4, substitute FLOAT4) returns FLOAT4
NANVL(expr FLOAT8, substitute FLOAT8) returns FLOAT8
NANVL(expr NUMERIC, substitute NUMERIC) returns NUMERIC
NANVL(expr FLOAT4, substitute VARCHAR) returns FLOAT4

```

```
NANVL(expr FLOAT8, substitute VARCHAR) returns FLOAT8
NANVL(expr NUMERIC, substitute VARCHAR) returns NUMERIC
```

### General rules

- NANVL returns a substitute value when the specified value is not a number (NaN). The substitute value can be either a number or a string that can be converted to a number.
- For *expr* and *substitute*, specify a numeric data type. If *expr* and *substitute* have different data types, they will be converted to the data type with greater length or precision, and that is the data type that will be returned.
- For *substitute*, you can also specify a string indicating the numeric value.
- The data type used for the return value if a string is specified for the substitute value will be the same as the data type of *expr*.

### Example

In the following example, "0" is returned if the value of col1 in table t1 is a NaN value.

```
SELECT col1, NANVL(col3,0) FROM t1;
 col1 | nanvl
-----+-----
 2001 |      0
(1 row)
```

## F.56.5.5.4. NVL

### Description

Returns a substitute value when a value is NULL.

### Syntax

```
NVL(expr1 anyelement, expr2 anyelement) return anyelement
```

### General rules

- NVL returns a substitute value when the specified value is NULL. When *expr1* is NULL, *expr2* is returned. When *expr1* is not NULL, *expr1* is returned.
- Specify the same data types for *expr1* and *expr2*. However, if a constant is specified in *expr2*, and the data type can also be converted by *expr1*, different data types can be specified. When this happens, the conversion by *expr2* is done to suit the data type in *expr1*, so the value of *expr2* returned when *expr1* is a NULL value will be the value converted in the data type of *expr1*. This is not necessary for types (numeric, int) and (bigint, int).

### Example

In the following example, "IS NULL" is returned if the value of col1 in table t1 is a NULL value.

```
SELECT col2, NVL(col1, 'IS NULL') "nv1" FROM t1;
 col2 |   nv1
-----+-----
  aaa | IS NULL
```

(1 row)

### F.56.5.5.5. NVL2

#### Description

Returns a substitute value based on whether a value is NULL or not NULL.

#### Syntax

```
NVL2(expr anyelement, substitute1 anyelement, substitute2  
anyelement) return anyelement
```

#### General rules

- NVL2 returns a substitute value based on whether the specified value is NULL or not NULL. When *expr* is NULL, *substitute2* is returned. When it is not NULL, *substitute1* is returned.
- Specify the same data types for *expr*, *substitute1*, and *substitute2*. However, if a literal is specified in *substitute1* or *substitute2*, and the data type can also be converted by *expr*, different data types can be specified. When this happens, *substitute1* or *substitute2* is converted to suit the data type in *expr*, so the value of *substitute2* returned when *expr* is a NULL value will be the value converted to the data type of *expr*.

#### Example

In the following example, if a value in column *col1* in table *t1* is NULL, "IS NULL" is returned, and if not NULL, "IS NOT NULL" is returned.

```
SELECT col2, NVL2(col1, 'IS NOT NULL', 'IS NULL') FROM t1;  
col2 |  nv12  
-----+-----  
aaa  |  IS NULL  
bbb  |  IS NOT NULL  
(2 row)
```

### F.56.5.6. Aggregate Functions

The following aggregation functions are supported:

- ANY\_VALUE
- BIT\_AND\_AGG
- BIT\_OR\_AGG
- BIT\_XOR\_AGG
- KURTOSIS\_POP
- KURTOSIS\_SAMP
- LISTAGG
- MEDIAN
- SKEWNESS\_POP

- SKEWNESS\_SAMP

### F.56.5.6.1. ANY\_VALUE

#### Description

ANY\_VALUE returns a single non-deterministic value of expr.

#### Syntax

```
ANY_VALUE(expr anyelement) returns anyelement
```

#### General rules

- Use ANY\_VALUE to optimize a query that has a GROUP BY clause. ANY\_VALUE returns a value of an expression in a group. It is optimized to return the first value.
- It ensures that there are no comparisons for any incoming row and also eliminates the necessity to specify every column as part of the GROUP BY clause.
- Because it does not compare values, ANY\_VALUE returns a value more quickly than MIN or MAX in a GROUP BY query.
- Returns any value within each group based on the GROUP BY specification. Returns NULL if all rows in the group have NULL expression values.
- The result of ANY\_VALUE is not deterministic.

#### Note

- If using ANY\_VALUE, it is necessary to specify "oracle" for search\_path in advance.

#### See

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

#### Example

```
create table test_any_value(key1 int, key2 int);
insert into test_any_value values(1, 1);
select any_value(key2) from test_any_value group by key1;
 any_value
-----
          1
(1 row)
```

### F.56.5.6.2. BIT\_AND\_AGG

#### Description

BIT\_AND\_AGG is a bitwise aggregation function that returns the result of a bitwise AND operation.

#### Syntax

BIT\_AND\_AGG(numeric) returns int

**General rules**

- You can use BIT\_AND\_AGG as part of a GROUP BY query, window function, or as an analytical function.
- For a given set of values, the result of a bitwise aggregate is always deterministic and independent of ordering.
- The data type of the return value is int.

**Note**

- If using BIT\_AND\_AGG, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
select bit_and_agg(column1) from (values (1),(2),(4),(8)) x;
 bit_and_agg
-----
          0
(1 row)
```

**F.56.5.6.3. BIT\_OR\_AGG****Description**

BIT\_OR\_AGG is a bitwise aggregation function that returns the result of a bitwise OR operation.

**Syntax**

BIT\_OR\_AGG(numeric) returns int

**General rules**

- You can use BIT\_OR\_AGG as part of a GROUP BY query, window function, or as an analytical function.
- For a given set of values, the result of a bitwise aggregate is always deterministic and independent of ordering.
- The data type of the return value is int.

**Note**

- If using BIT\_OR\_AGG, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.

- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
select bit_or_agg(column1) from (values (1),(2),(4),(8)) x;
   bit_or_agg
-----
              15
(1 row)
```

**F.56.5.6.4. BIT\_XOR\_AGG****Description**

BIT\_XOR\_AGG is a bitwise aggregation function that returns the result of a bitwise XOR operation.

**Syntax**

```
BIT_XOR_AGG(numeric) returns int
```

**General rules**

- You can use BIT\_XOR\_AGG as part of a GROUP BY query, window function, or as an analytical function.
- For a given set of values, the result of a bitwise aggregate is always deterministic and independent of ordering.
- The data type of the return value is int.

**Note**

- If using BIT\_XOR\_AGG, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using oracle" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
select bit_xor_agg(column1) from (values (1),(3),(4),(8)) x;
   bit_xor_agg
-----
              14
(1 row)
```

**F.56.5.6.5. KURTOSIS\_POP****Description**

The population kurtosis function KURTOSIS\_POP is primarily used to determine the characteristics of outliers in a given distribution.

**Syntax**

```
KURTOSIS_POP(numeric) returns numeric
```

**General rules**

- NULL values in expr are ignored.
- Returns NULL if all rows in the group have NULL expr values.
- Returns 0 if there are one or two rows in expr.
- For a given set of values, the result of population kurtosis (KURTOSIS\_POP) and sample kurtosis (KURTOSIS\_SAMP) are always deterministic. However, the values of KURTOSIS\_POP and KURTOSIS\_SAMP differ. As the number of values in the data set increases, the difference between the computed values of KURTOSIS\_SAMP and KURTOSIS\_POP decreases.

**Note**

- If using the KURTOSIS\_POP function, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
select kurtosis_pop(column1) from (values (1),(2),(4),(8)) x;
      kurtosis_pop
-----
-1.09897920604914942667
(1 row)
```

**F.56.5.6.6. KURTOSIS\_SAMP****Description**

The sample kurtosis function KURTOSIS\_SAMP is primarily used to determine the characteristics of outliers in a given distribution.

**Syntax**

```
KURTOSIS_SAMP(numeric) returns numeric
```

**General rules**

- NULL values in expr are ignored.
- Returns NULL if all rows in the group have NULL expr values.
- Returns 0 if there are one or two rows in expr.

- For a given set of values, the result of sample kurtosis (KURTOSIS\_SAMP) and population kurtosis (KURTOSIS\_POP) are always deterministic. However, the values of KURTOSIS\_SAMP and KURTOSIS\_POP differ. As the number of values in the data set increases, the difference between the computed values of KURTOSIS\_SAMP and KURTOSIS\_POP decreases.

**Note**

- If using the KURTOSIS\_SAMP function, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
select kurtosis_samp(column1) from (values (1),(2),(4),(8)) x;
      kurtosis_samp
-----
0.7576559546313793
(1 row)
```

### F.56.5.6.7. LISTAGG

**Description**

Returns a concatenated, delimited list of string values.

**Syntax**

```
LISTAGG(strExpr TEXT) returns TEXT
LISTAGG(strExpr TEXT, delimiter TEXT) [ ]returns TEXT
LISTAGG(strExpr TEXT, delimiter TEXT ON OVERFLOW TRUNCATE)
[ ]returns TEXT
LISTAGG(strExpr TEXT, delimiter TEXT ON OVERFLOW ERROR)
[ ]returns TEXT
```

**General rules**

- LISTAGG concatenates and delimits a set of string values and returns the result.
- For *delimiter*, specify a string. If the delimiter is omitted, a list of strings without a delimiter is returned.
- In LightDB, LISTAGG support using distinct in function with within group clauses. e.g: LISTAGG(distinct c1) within group(order by c1)
- In LightDB, LISTAGG support using on overflow truncate# e.g: LISTAGG(c1, ':' on overflow truncate)
- In LightDB, LISTAGG support using on overflow error# e.g: LISTAGG(c1, ':' on overflow error)
- In LightDB, LISTAGG support using within group clauses with over clauses. In this scenario we cannot use distinct in function yet. e.g: LISTAGG(c1) within group(order by c1) over(partition by c2)

- The data type of the return value is TEXT.

### Example

In the following example, the result with values of column col2 in table t1 delimited by ':' is returned.

```
SELECT LISTAGG(col2,':') FROM t1;
      listagg
-----
AAAAA:BBBBB:CCCCC
(1 row)
```

In the following example, using within group with over.

```
CREATE TABLE EMP
( EMPNO    NUMBER(4, 0),
  ENAME    VARCHAR2(10),
  JOB      VARCHAR2(9),
  MGR      NUMBER(4, 0),
  HIREDATE DATE,
  SAL      NUMBER(7, 2),
  COMM     NUMBER(7, 2),
  DEPTNO   NUMBER(2, 0),
  DNAME    VARCHAR2(100),
  CONSTRAINT PK_EMP PRIMARY KEY (EMPNO)
);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7369, 'SMITH', 'CLERK', 7902,
  to_date('1980-12-17','yyyy-mm-dd'), 800.00, null, 20, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7499, 'ALLEN', 'SALESMAN', 7698,
  to_date('1981-02-20','yyyy-mm-dd'), 1600.00, 300.00, 30, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7521, 'WARD', 'SALESMAN', 7698,
  to_date('1981-02-22','yyyy-mm-dd'), 1250.00, 500.00, 30, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7566, 'JONES', 'MANAGER', 7839,
  to_date('1981-04-02','yyyy-mm-dd'), 2975.00, null, 20, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7654, 'MARTIN', 'SALESMAN', 7698,
  to_date('1981-09-28','yyyy-mm-dd'), 1250.00, 1400.00, 30, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7698, 'BLAKE', 'MANAGER', 7839,
  to_date('1981-05-01','yyyy-mm-dd'), 2850.00, null, 30, null);
insert into EMP (EMPNO, ENAME, JOB, MGR, HIREDATE, SAL, COMM,
  DEPTNO, DNAME) values (7782, 'CLARK', 'MANAGER', 7839,
  to_date('1981-06-09','yyyy-mm-dd'), 2450.00, null, 10, null);

### F.56.5.6.8. MEDIAN

#### Description

Calculates the median of a set of numbers.

#### Syntax

```
MEDIAN(numExpr REAL) returns REAL
MEDIAN(numExpr DOUBLE PRECISION) returns DOUBLE PRECISION
```

#### General rules

- MEDIAN returns the median of a set of numbers.
- The numbers must be numeric data type.
- The data type of the return value will be REAL if the numbers are REAL type, or DOUBLE PRECISION if any other type is specified.

**Example**

In the following example, the median of column col3 in table t1 is returned.

```
SELECT MEDIAN(col3) FROM t1;
   median
-----
      2000
(1 row)
```

**F.56.5.6.9. SKEWNESS\_POP****Description**

SKEWNESS\_POP is an aggregate function that is primarily used to determine symmetry in a given distribution.

**Syntax**

```
SKEWNESS_POP(numeric) returns numeric
```

**General rules**

- NULL values in expr are ignored.
- Returns NULL if all rows in the group have NULL expr values.
- Returns 0 if there are one or two rows in expr.
- For a given set of values, the result of population skewness (SKEWNESS\_POP) and sample skewness (SKEWNESS\_SAMP) are always deterministic. However, the values of SKEWNESS\_POP and SKEWNESS\_SAMP differ. As the number of values in the data set increases, the difference between the computed values of SKEWNESS\_SAMP and SKEWNESS\_POP decreases.

**Note**

- If using the SKEWNESS\_POP function, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

```
SELECT SKEWNESS_POP(column1) from (values (1),(2),(4),(8)) x;
   skewness_pop
-----
0.65680773449969915746
(1 row)
```

### F.56.5.6.10. SKEWNESS\_SAMP

#### Description

SKEWNESS\_SAMP is an aggregate function that is primarily used to determine symmetry in a given distribution.

#### Syntax

```
SKEWNESS_SAMP(numeric) returns numeric
```

#### General rules

- NULL values in expr are ignored.
- Returns NULL if all rows in the group have NULL expr values.
- Returns 0 if there are one or two rows in expr.
- For a given set of values, the result of population skewness (SKEWNESS\_POP) and sample skewness (SKEWNESS\_SAMP) are always deterministic. However, the values of SKEWNESS\_POP and SKEWNESS\_SAMP differ. As the number of values in the data set increases, the difference between the computed values of SKEWNESS\_SAMP and SKEWNESS\_POP decreases.

#### Note

- If using the SKEWNESS\_SAMP function, it is necessary to specify "oracle" for search\_path in advance.

#### See

- Refer to "Notes on Using oracle" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

#### Example

```
SELECT SKEWNESS_SAMP(column1) from (values (1),(2),(4),(8)) x;  
      skewness_samp  
-----  
1.13762436695768880892  
(1 row)
```

### F.56.5.7. Functions That Return Internal Information

The following functions that return internal information are supported:

- DUMP
- NLS\_CHARSET\_ID
- NLS\_CHARSET\_NAME
- SYS\_CONTEXT
- USERENV

### F.56.5.7.1. DUMP

#### Description

Returns internal information of a value.

#### Syntax

```
DUMP(expr TEXT) returns VARCHAR
DUMP(expr TEXT, fmt INTEGER) returns VARCHAR
```

#### General rules

- DUMP returns the internal information of the values specified in expressions in a display format that is in accordance with the output format.
- The internal code (Typ) of the data type, the data length (Len) and the internal expression of the data are output as internal information.
- Any data type can be specified for the expressions.
- The display format (base *n*) of the internal expression of the data is specified for the output format. The base numbers that can be specified are 8, 10, and 16. If omitted, 10 is used as the default.
- The data type of the return value is VARCHAR.

#### Note

The information output by DUMP will be the complete internal information. Therefore, the values may change due to product updates, and so on.

#### Example

In the following example, the internal information of column `coll` in table `t1` is returned.

```
SELECT coll, DUMP(coll) FROM t1;
coll | dump
-----+-----
1001 | Typ=25 Len=8: 32,0,0,0,49,48,48,49
1002 | Typ=25 Len=8: 32,0,0,0,49,48,48,50
1003 | Typ=25 Len=8: 32,0,0,0,49,48,48,51
(3 row)
```

### F.56.5.7.2. NLS\_CHARSET\_ID

#### Description

NLS\_CHARSET\_ID returns the character set ID number corresponding to character set name string.

#### Syntax

```
NLS_CHARSET_ID(str text) returns integer
```

#### General rules

- Invalid character set names return null.

**Note**

- The character set name is from Oracle, use this function only for compatibility.
- If using the NLS\_CHARSET\_ID function, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using oraofce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

The following example returns the character set ID of a character set:

```
SELECT NLS_CHARSET_ID( 'AL32UTF8' ) FROM DUAL;
 nls_charset_id
-----
                873
(1 row)
```

**F.56.5.7.3. NLS\_CHARSET\_NAME****Description**

NLS\_CHARSET\_NAME returns the name of the character set corresponding to ID number number.

**Syntax**

```
NLS_CHARSET_NAME(str text) returns integer
```

**General rules**

- If number is not recognized as a valid character set ID, then this function returns null.

**Note**

- The character set name is from Oracle, use this function only for compatibility.
- If using the NLS\_CHARSET\_NAME function, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using oraofce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

The following example returns the character set corresponding to character set ID number 873:

```
SELECT NLS_CHARSET_NAME( 873 ) FROM DUAL;
 nls_charset_name
```

```
-----
AL32UTF8
(1 row)
```

#### F.56.5.7.4. SYS\_CONTEXT

##### Description

Returns the value of parameter associated with the context namespace at the current instant

##### Syntax

```
SYS_CONTEXT(namespace text, parameter text, length int4
default 256) returns text
```

##### General rules

- For namespace and parameter, you can specify either a string or an expression that resolves to a string designating a namespace or an attribute.
- The context namespace must already have been created, and the associated parameter and its value must also have been set.
- The namespace must be a valid identifier. The parameter name can be any string. It is not case sensitive, but it cannot exceed 4000 bytes in length.

##### Note

LightDB provides the following built-in namespaces:

- USERENV - Describes the current session. The predefined parameters of namespace USERENV are listed in table Table F.116
- SYS\_SESSION\_ROLES - Indicates whether a specified role is currently enabled for the session.

**Table F.116. Predefined Parameters of Namespace USERENV**

Parameters	Overview
CLIENT_IDENTIFIER	The name of the program used for the database session
CLIENT_INFO	The name of the program used for the database session
CLIENT_PROGRAM_NAME	The name of the program used for the database session
CDB_NAME	Current database
CON_ID	Always 1
CON_NAME	Current database
CURRENT_SCHEMA	Current schema
CURRENT_SCHEMAID	Current schema id
CURRENT_USER	Current user
CURRENT_USERID	Current user id
DATABASE_ROLE	The role is one of the following: PRIMARY, PHYSICAL STANDBY

Parameters	Overview
DB_NAME	Current database
DB_UNIQUE_NAME	Current database
HOST	Name of the host machine from which the client has connected
INSTANCE	Always 1
INSTANCE_NAME	Always 'LightDB'
IP_ADDRESS	IP address of the machine from which the client is connected
ISDBA	Returns TRUE if the user has been authenticated as having DBA privileges
LANG	The abbreviated name for the language, a shorter form than the existing 'LANGUAGE' parameter
LANGUAGE	The language and territory currently used by your session, along with the database character set
MODULE	The name of the program used for the database session
NETWORK_PROTOCOL	Network protocol being used for communication
NLS_DATE_FORMAT	The date format for the session
ORACLE_HOME	The full path name for the data home directory
PID	Current process ID
SERVER_HOST	listen_addresses
SERVICE_NAME	Current database
SESSION_USER	Current user
SESSION_USERID	Current user id
SESSIONID	Current session process id
SID	Current session process id

**Note**

- If using SYS\_CONTEXT, it is necessary to specify "oracle" for search\_path in advance.

**See**

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

**Example**

The following statement returns the name of the user who logged onto the database:

```
SELECT SYS_CONTEXT ( 'USERENV', 'SESSION_USER' ) FROM DUAL;
 sys_context
-----
 lightdb
(1 row)
```

### F.56.5.7.5. USERENV

#### Description

Returns information about the current session

#### Syntax

```
USERENV(parameter text) returns text
```

#### General rules

- This information can be useful for writing an application-specific audit trail table or for determining the language-specific characters currently used by your session.
- Table Table F.116 describes the values for the parameter argument.

#### Note

- If using USERENV, it is necessary to specify "oracle" for search\_path in advance.

#### See

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

#### Example

The following example returns the LANGUAGE parameter of the current session:

```
SELECT USERENV( 'LANGUAGE' ) "Language" FROM DUAL ;
  Language
-----
en_US.UTF-8
(1 row)
```

### F.56.5.8. Datetime Operator

The following datetime operators are supported for the DATE type of orafce.

**Table F.117. Datetime operator**

Operation	Example	Result
+	DATE'2016/01/01' + 10	2016-01-11 00:00:00
-	DATE'2016/03/20' - 35	2016-02-14 00:00:00
-	DATE'2016/09/01' - DATE'2015/12/31'	245

#### Note

If using datetime operators for the DATE type of orafce, it is necessary to specify "oracle" for search\_path in advance.

#### See

Refer to "Notes on Using orafce" for information on how to edit search\_path.

## F.56.5.9. Other functions

The following functions is used for other purpose:

- EMPTY\_CLOB
- EMPTY\_BLOB
- ORA\_HASH
- VSIZE
- DEPS\_SAVE\_AND\_DROP\_DEPENDENCIES/DEPS\_RESTORE\_DEPENDENCIES
- PLVSTR.IS\_PREFIX
- PLVDATE.ISLEAPYEAR

### F.56.5.9.1. EMPTY\_CLOB

#### Description

Return an empty CLOB

#### Syntax

```
EMPTY_CLOB() RETURNS clob
```

#### General rules

- can be used to initialize a CLOB variable, or, in an INSERT or UPDATE statement, to initialize a CLOB column or attribute to EMPTY. EMPTY means that the CLOB is initialized, but not populated with data.
- has a length of zero but is not null.

#### Note

- If using the EMPTY\_CLOB function, it is necessary to specify "oracle" for search\_path in advance.

#### See

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

#### Example

```
select length(empty_clob()) FROM DUAL;
length
-----
      0
(1 row)
```

```
select count(*) from dual where empty_clob() is null;
count
-----
```

```
      0
(1 row)
```

```
create table foo (a int, b clob default empty_clob());
insert into foo(a) values(1);
insert into foo values (2, 'hello');
select count(*) from foo where b is not null;
  count
-----
```

```
      2
(1 row)
select count(*) from foo where length(b) > 0;
  count
-----
```

```
      1
(1 row)
```

### F.56.5.9.2. EMPTY\_BLOB

#### Description

Return an empty BLOB

#### Syntax

```
EMPTY_BLOB() RETURNS blob
```

#### General rules

- can be used to initialize a BLOB variable, or, in an INSERT or UPDATE statement, to initialize a BLOB column or attribute to EMPTY. EMPTY means that the BLOB is initialized, but not populated with data.
- has a length of zero but is not null.

#### Example

```
select length(empty_blob()) FROM DUAL;
  length
-----
      0
(1 row)
```

```
select count(*) from dual where empty_blob() is null;
  count
-----
      0
(1 row)
```

```
create table foo (a int, b blob default empty_blob());
insert into foo(a) values(1);
```

```
insert into foo values (2, to_blob('616263'));
select count(*) from foo where b is not null;
  count
-----
       2
(1 row)
select count(*) from foo where length(b) > 0;
  count
-----
       1
(1 row)
```

### F.56.5.9.3. ORA\_HASH

#### Description

ORA\_HASH is a function that computes a hash value for a given expression. This function is useful for operations such as analyzing a subset of data and generating a random sample.

#### Syntax

```
ORA_HASH(p_data anyelement, p_buckets int4, p_seed int4)
RETURNS int
```

#### General rules

- The p\_data argument determines the data for which you want LightDB Database to compute a hash value. There are no restrictions on the length of data represented by expr, which commonly resolves to a column name.
- The optional p\_buckets argument determines the maximum bucket value returned by the hash function. You can specify any value between 0 and 2147483647. The default is 0.
- The optional p\_seed argument enables LightDB to produce many different results for the same set of data. LightDB applies the hash function to the combination of expr and p\_seed. You can specify any value between 0 and 2147483647. The default is 0.
- The data type of the return value is int.

#### Note

- If using ORA\_HASH, it is necessary to specify "oracle" for search\_path in advance.

#### See

- Refer to "Notes on Using oracle" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

#### Example

```
select ora_hash('abcdAbcdasd'::text) FROM DUAL;
  ora_hash
-----
 303228277
(1 row)
```

#### F.56.5.9.4. VSIZE

##### Description

VSIZE returns the number of bytes in the internal representation of expr. If expr is null, then this function returns null.

##### Syntax

```
VSIZE(anyelement) RETURNS integer
```

##### General rules

- Same with pg\_column\_size.

##### Note

- If using VSIZE, it is necessary to specify "oracle" for search\_path in advance.

##### See

- Refer to "Notes on Using orafce" for information on how to edit search\_path.
- Refer to "Server Administration" > "Server Configuration" > "Setting Parameters" in the LightDB Documentation for information on how to set the server parameters.

##### Example

```
select vsize(123456789) FROM DUAL;
 vsize
-----
      4
(1 row)
```

#### F.56.5.9.5. DEPS\_SAVE\_AND\_DROP\_DEPENDENCIES/ DEPS\_RESTORE\_DEPENDENCIES

##### Description

These functions are used to modify tables that have view dependencies. Recursively backup all dependent views, then modify base tables, then recreate all backedup views.

DEPS\_SAVE\_AND\_DROP\_DEPENDENCIES save and drop dependencies for table.

DEPS\_RESTORE\_DEPENDENCIES restore dependencies for table.

##### Syntax

```
DEPS_SAVE_AND_DROP_DEPENDENCIES(name, name default
current_schema()::name, jsonb default '{} '::jsonb) RETURNS void
DEPS_RESTORE_DEPENDENCIES(name, name default
current_schema()::name, jsonb default '{} '::jsonb)
```

##### General rules

- Create under lt\_catalog.

- dependencies is saved in lt\_catalog.deps\_saved\_ddl table.
- dry\_run Run without actually dropping dependencies, default false.
- verbose Show debug log, , default false.
- populate\_materialized\_view Enable or disable materialized view refresh-on-create via WITH [NO] DATA flag, default false.

**Note**

- If using DEPS\_SAVE\_AND\_DROP\_DEPENDENCIES/DEPS\_RESTORE\_DEPENDENCIES, it is not necessary to specify "oracle" for search\_path in advance.

**Example**

```
create table test_t(key1 int);
create view test_t_v as select * from test_t;
begin;
select deps_save_and_drop_dependencies('test_t');
alter table test_t modify key1 number;
select * from deps_restore_dependencies('test_t');
commit;
```

**F.56.5.9.6. PLVSTR.IS\_PREFIX**

**Description**

PLVSTR.IS\_PREFIX return true if a string or number is the prefix of another string or number.

**Syntax**

```
PLVSTR.IS_PREFIX(p bigint, prefix bigint) RETURNS boolean
PLVSTR.IS_PREFIX(p integer, prefix integer) RETURNS boolean
PLVSTR.IS_PREFIX(p text, prefix text) RETURNS boolean
```

**General rules**

- This function can be useful for testing whether a string or number begins with something.

**Example**

```
select plvstr.is_prefix(111, 11) FROM DUAL;
is_prefix
-----
t
(1 row)
select plvstr.is_prefix('abc', 'AB') from dual;
is_prefix
-----
f
(1 row)
```

**F.56.5.9.7. PLVDATE.ISLEAPYEAR**

**Description**

PLVDATE.ISLEAPEAR return true if the date is a leap year.

**Syntax**

```
PLVDATE.ISLEAPYEAR(date) RETURNS boolean
```

**Example**

```
select plvdate.isleapyear(date '2023-01-01') FROM DUAL;  
isleapyear
```

```
-----  
f
```

```
select plvdate.isleapyear(date '2020-01-01') from dual;  
isleapyear
```

```
-----  
t
```

## F.56.6. Package Reference

A "package" is a group of features, brought together by schemas, that have a single functionality, and are used by calling from PL/pgSQL.

The following packages are supported:

- DBMS\_ALERT
- DBMS\_ASSERT
- DBMS\_LOB
- DBMS\_OUTPUT
- DBMS\_PIPE
- DBMS\_RANDOM
- DBMS\_UTILITY
- DBMS\_JOB
- DBMS\_LOCK
- DBMS\_METADATA
- DBMS\_OBFUSCATION\_TOOLKIT
- DBMS\_SNAPSHOT
- UTL\_FILE
- UTL\_RAW
- UTL\_URL
- UTL\_ENCODE

To call the different functionalities from PL/pgSQL, use the `PERFORM` statement or `SELECT` statement, using the package name to qualify the name of the functionality. Refer to the explanations for each of the package functionalities for information on the format for calling.

### F.56.6.1. DBMS\_ALERT

#### Overview

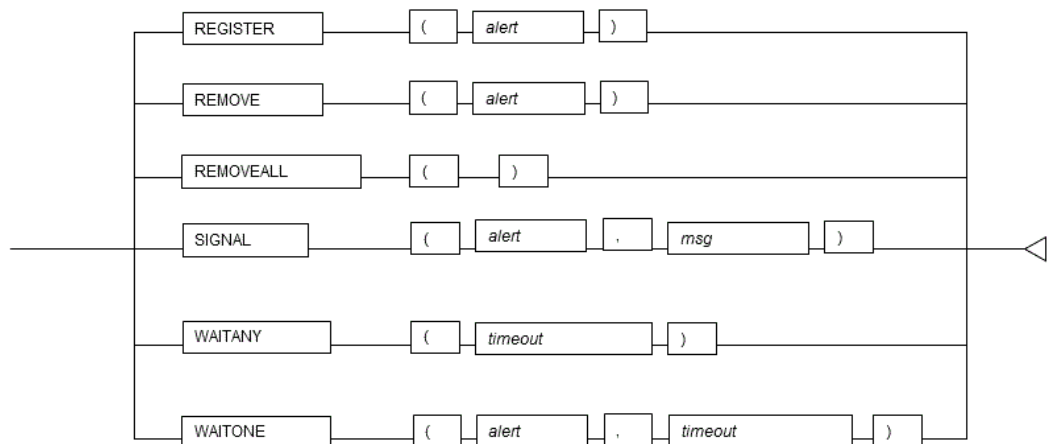

The `DBMS_ALERT` package sends alerts from a PL/pgSQL session to multiple other PL/pgSQL sessions.

This package can be used when processing 1:N, such as when notifying alerts from a given PL/pgSQL session to another PL/pgSQL session at the same time.

**Table F.118. DBMS\_ALERT Features**

Feature	Description
REGISTER	Registers the specified alert.
REMOVE	Removes the specified alert.
REMOVEALL	Removes all alerts from a session.
SIGNAL	Notifies alerts.
WAITANY	Waits for notification of any alerts for which a session is registered.
WAITONE	Waits for notification of a specific alert for which a session is registered.

#### Syntax

#### F.56.6.1.1. Description of Features

This section explains each feature of `DBMS_ALERT`.

##### REGISTER

- `REGISTER` registers the specified alert to a session. By registering alerts to a session, `SIGNAL` notifications can be received.
- Specify the name of the alert.
- Alerts are case-sensitive.
- Multiple alerts can be registered within a single session. If registering multiple alerts, call `REGISTER` for each alert.

### Example

```
PERFORM DBMS_ALERT.REGISTER('sample_alert');
```

### REMOVE

- REMOVE removes the specified alert from a session.
- Specify the name of the alert.
- Alerts are case-sensitive.
- The message left by the alert will be removed.

### Example

```
PERFORM DBMS_ALERT.REMOVE('sample_alert');
```

### REMOVEALL

- REMOVEALL removes all alerts registered within a session.
- All messages left by the alerts will be removed.

### Example

```
PERFORM DBMS_ALERT.REMOVEALL();
```

### SIGNAL

- SIGNAL sends a message notification for the specified alert.
- Specify the name of the alert for which message notifications are sent.
- Alerts are case-sensitive.
- In the message, specify the alert message for notifications.
- Message notifications are not complete at the stage when SIGNAL is executed. Message notifications are sent upon committing the transaction. Message notifications are discarded if a rollback is performed after SIGNAL is executed.
- If message notifications are sent for the same alert from multiple sessions, the messages will be accumulated without being removed.

### Example

```
PERFORM DBMS_ALERT.SIGNAL('ALERT001', 'message001');
```

### Note

If SIGNAL is issued continuously and the accumulated messages exceed a certain amount, an insufficient memory error may be output. If the memory becomes insufficient, call AITANY or WAITONE to receive an alert, and reduce the accumulated messages.

**WAITANY**

- WAITANY waits for notification of any alerts registered for a session.
- Specify the maximum wait time *timeout* in seconds to wait for an alert.
- Use a SELECT statement to obtain the notified information, which is stored in the name, message and status columns.
- The name column stores the alert names. The data type of name is TEXT.
- The message column stores the messages of notified alerts. The data type of message is TEXT.
- The status column stores the status code returned by the operation: 0-an alert occurred; 1-a timeout occurred. The data type of status is INTEGER.

**Example**

```
DECLARE
    alert_name          TEXT := 'sample_alert';
    alert_message       TEXT;
    alert_status        INTEGER;
BEGIN
    SELECT name,message,status INTO
    alert_name,alert_message,alert_status FROM DBMS_ALERT.WAITANY(60);
```

**WAITONE**

- WAITONE waits for notification of the specified alert.
- Specify the name of the alert to wait for.
- Alerts are case-sensitive.
- Specify the maximum wait time *timeout* in seconds to wait for the alert.
- Use a SELECT statement to obtain the notified information, which is stored in the message and status columns.
- The message column stores the messages of notified alerts. The data type of message is TEXT.
- The status column stores the status code returned by the operation: 0-an alert occurred; 1-a timeout occurred. The data type of status is INTEGER.

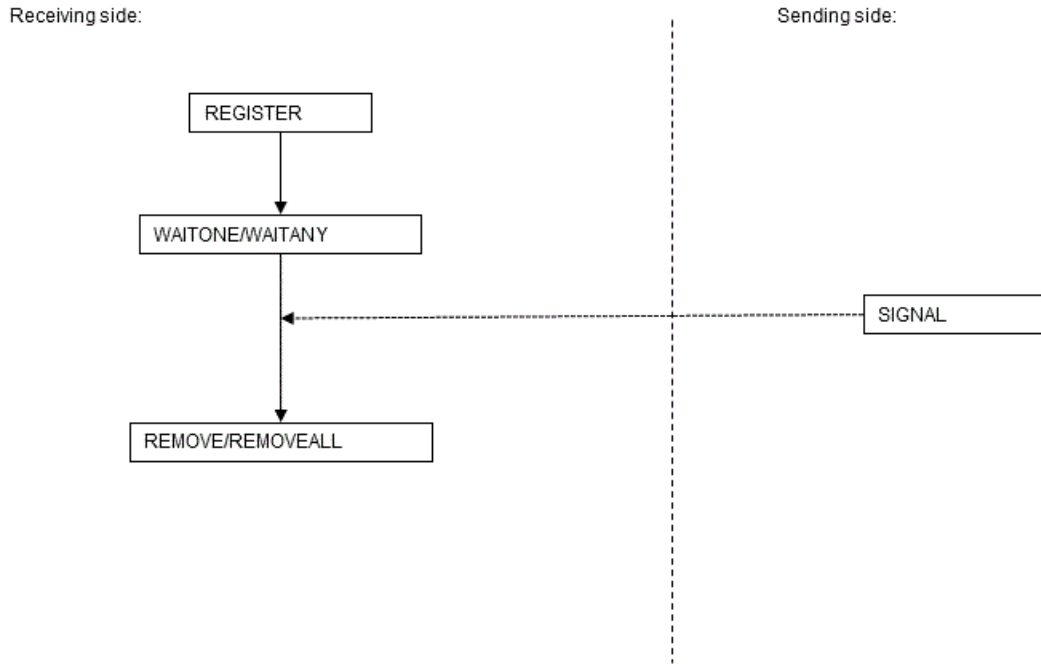

**Example**

```
DECLARE
    alert_message       TEXT;
    alert_status        INTEGER;
BEGIN
    SELECT message,status INTO alert_message,alert_status FROM
    DBMS_ALERT.WAITONE('sample_alert', 60);
```

**F.56.6.1.2. Usage Example**

Below is a usage example of the processing flow of DBMS\_ALERT.

**DBMS\_ALERT flow**

**Note**

- The target of message notifications by `SIGNAL` is sessions for which `REGISTER` is executed at the time of executing `SIGNAL`.
- On the receiving side, always ensure that `REMOVE` or `REMOVEALL` is used to remove alerts as soon as the alerts are no longer needed. If a session is closed without removing the alerts, it may no longer be possible to receive a `SIGNAL` for alerts of the same name in another session.
- `DBMS_ALERT` and `DBMS_PIPE` use the same memory environment. Therefore, when insufficient memory is detected for `DBMS_PIPE`, it is possible that insufficient memory will also be detected for `DBMS_ALERT`.

**Usage example**

- Sending side

```
CREATE FUNCTION send_dbms_alert_exe() RETURNS VOID AS $$
BEGIN
    PERFORM DBMS_ALERT.SIGNAL('sample_alert','SIGNAL ALERT');
END;
$$ LANGUAGE plpgsql;
SELECT send_dbms_alert_exe();
DROP FUNCTION send_dbms_alert_exe();
```

- Receiving side

```
CREATE FUNCTION receive_dbms_alert_exe() RETURNS VOID AS $$
DECLARE
    alert_name TEXT := 'sample_alert';
    alert_message TEXT;
    alert_status INTEGER;
BEGIN
    PERFORM DBMS_ALERT.REGISTER(alert_name);
```

```

SELECT message,status INTO alert_message,alert_status FROM
DBMS_ALERT.WAITONE(alert_name,300);
RAISE NOTICE 'Message : %', alert_message;
RAISE NOTICE 'Status : %', alert_status;
PERFORM DBMS_ALERT.REMOVE(alert_name);
END;
$$ LANGUAGE plpgsql;
SELECT receive_dbms_alert_exe();
DROP FUNCTION receive_dbms_alert_exe();

```

## F.56.6.2. DBMS\_ASSERT

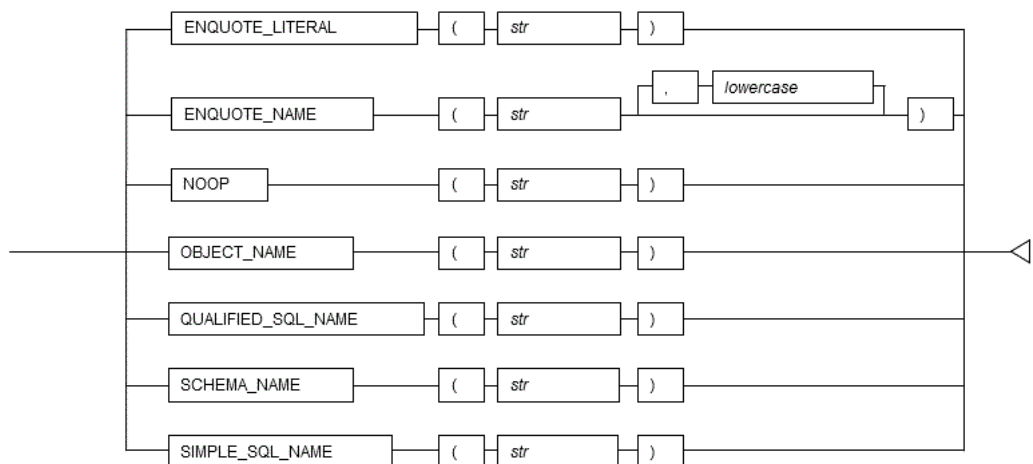

### Overview

Performs verification of the properties of input values in PL/pgSQL.

**Table F.119. DBMS\_ASSERT Features**

Feature	Description
ENQUOTE_LITERAL	Returns the specified string enclosed in single quotation marks.
ENQUOTE_NAME	Returns the specified string enclosed in double quotation marks.
NOOP	Returns the specified string as is.
OBJECT_NAME	Verifies if the specified string is a defined identifier.
QUALIFIED_SQL_NAME	Verifies if the specified string is in the appropriate format as an identifier.
SCHEMA_NAME	Verifies if the specified string is a defined schema.
SIMPLE_SQL_NAME	Verifies if the specified string is in the appropriate format as a single identifier.

### Syntax

### F.56.6.2.1. Description of Features

This section explains each feature of DBMS\_ASSERT.

**ENQUOTE\_LITERAL**

- ENQUOTE\_LITERAL returns the specified string enclosed in single quotation marks.
- Specify a string enclosed in single quotation marks.
- The data type of the return value is VARCHAR.

**Example**

```
DECLARE
    q_literal    VARCHAR(256);
BEGIN
    q_literal := DBMS_ASSERT.ENQUOTE_LITERAL('literal_word');
```

**ENQUOTE\_NAME**

- ENQUOTE\_NAME returns the specified string enclosed in double quotation marks.
- Specify a string enclosed in double quotation marks.
- For lowercase conversion, specify TRUE or FALSE. Specify TRUE to convert uppercase characters in the string to lowercase. If FALSE is specified, conversion to lowercase will not take place. The default is TRUE.
- If all the characters in the string are lowercase, they will not be enclosed in double quotation marks.
- The data type of the return value is VARCHAR.

**See**

Refer to "The SQL Language" > "Data Types" > "Boolean Type" in the LightDB Documentation for information on boolean type (TRUE/FALSE) values.

**Example**

```
DECLARE
    dq_literal    VARCHAR(256);
BEGIN
    dq_literal := DBMS_ASSERT.ENQUOTE_NAME('TBL001');
```

**NOOP**

- NOOP returns the specified string as is.
- Specify a string.
- The data type of the return value is VARCHAR.

**Example**

```
DECLARE
    literal    VARCHAR(256);
BEGIN
    literal := DBMS_ASSERT.NOOP('NOOP_WORD');
```

**OBJECT\_NAME**

- OBJECT\_NAME verifies if the specified string is a defined identifier.
- Specify the identifier for verification. If the identifier has been defined, the specified identifier will be returned. Otherwise, the following error will occur.

```
ERROR:  invalid object name
```

- The data type of the return value is VARCHAR.

#### Example

```
DECLARE
    object_name    VARCHAR(256);
BEGIN
    object_name := DBMS_ASSERT.OBJECT_NAME('SCM001.TBL001');
```

#### QUALIFIED\_SQL\_NAME

- QUALIFIED\_SQL\_NAME verifies if the specified string is in the appropriate format as an identifier.
- Specify the identifier for verification. If the string can be used as an identifier, the specified identifier will be returned. Otherwise, the following error will occur.

```
ERROR:  string is not qualified SQL name
```

- The data type of the return value is VARCHAR.

#### See

Refer to "The SQL Language" > "Lexical Structure" > "Identifiers and Key Words" in the LightDB Documentation for information on the formats that can be used as identifiers.

#### Example

```
DECLARE
    object_name    VARCHAR(256);
BEGIN
    object_name :=
DBMS_ASSERT.QUALIFIED_SQL_NAME('SCM002.TBL001');
```

#### SCHEMA\_NAME

- SCHEMA\_NAME verifies if the specified string is a defined schema.
- Specify a schema name for verification. If the schema has been defined, the specified schema name will be returned. Otherwise, the following error will occur.

```
ERROR:  invalid schema name
```

- The data type of the return value is VARCHAR.

#### Example

```

DECLARE
    schema_name    VARCHAR(256);
BEGIN
    schema_name := DBMS_ASSERT.SCHEMA_NAME('SCM001');

```

### **SIMPLE\_SQL\_NAME**

- SIMPLE\_SQL\_NAME verifies if the specified string is in the appropriate format as a single identifier.
- Specify an identifier for verification. If the specified string can be used as an identifier, the specified identifier will be returned. Otherwise, the following error will occur.

```

ERROR: string is not qualified SQL name

```

- The data type of the return value is VARCHAR.

### **See**

Refer to "The SQL Language" > "Lexical Structure" > "Identifiers and Key Words" in the LightDB Documentation for information on the formats that can be used as identifiers. Note that an error will occur if an identifier using fullwidth characters is specified. If fullwidth characters are included, specify a quoted identifier.

### **Example**

```

DECLARE
    simple_name    VARCHAR(256);
BEGIN
    simple_name := DBMS_ASSERT.SIMPLE_SQL_NAME('COL01');

```

## **F.56.6.2.2. Usage Example**

A usage example of DBMS\_ASSERT is shown below.

```

CREATE FUNCTION dbms_assert_exe() RETURNS VOID AS $$
DECLARE
    w_schema VARCHAR(20) := 'public';
    w_table  VARCHAR(20) := 'T1';
    w_object VARCHAR(40);
BEGIN
    PERFORM DBMS_ASSERT.NOOP(w_schema);
    PERFORM DBMS_ASSERT.SIMPLE_SQL_NAME(w_table);
    PERFORM DBMS_ASSERT.SCHEMA_NAME(w_schema);
    w_object := w_schema || '.' || w_table;
    PERFORM DBMS_ASSERT.QUALIFIED_SQL_NAME(w_object);
    PERFORM DBMS_ASSERT.OBJECT_NAME(w_object);
    RAISE NOTICE 'OBJECT      : %',
DBMS_ASSERT.ENQUOTE_LITERAL(w_object);
    RAISE NOTICE 'TABLE_NAME : %',
DBMS_ASSERT.ENQUOTE_NAME(w_table);
END;
$$

```

```

LANGUAGE plpgsql;
SELECT dbms_assert_exe();
DROP FUNCTION dbms_assert_exe();

```

### F.56.6.3. DBMS\_LOB

#### Overview

Some functions compatible with DBMS\_LOB package.

**Table F.120. DBMS\_LOB Features**

Feature	Description
INSTR	Returns starting index of specified LOB.
SUBSTR	Extracts the substring of LOB.
GETLENGTH	Returns the number of characters in the LOB.
APPEND	Appends the contents of the source LOB to the destination LOB.
CLOSE	Closes a previously opened internal or external LOB.(invalid)
COMPARE	Compares two entire LOBs or parts of two LOBs.
COPY	Copies all, or part, of the source LOB to the destination LOB.
CREATETEMPORAR	Creates a temporary BLOB or CLOB and its corresponding index in the user's default temporary tablespace.(invalid)
ERASE	Erases all or part of a LOB.
FREETEMPORARY	Erases all or part of a LOB.
OPEN	Frees the temporary BLOB or CLOB in the default temporary tablespace.(invalid)
READ	Reads data from the LOB starting at the specified offset.
TRIM	Trims the LOB value to the specified shorter length.
WRITE	Writes data to the LOB from a specified offset.
WRITEAPPEND	Writes a buffer to the end of a LOB.
COMPARE	Compares two entire LOBs or parts of two LOBs.

#### Syntax

```

INSTR(STR TEXT, PATT TEXT, START INTEGER DEFAULT 1, NTH
INTEGER DEFAULT 1) RETURNS INTEGER
INSTR(STR BLOB, PATT TEXT, START INTEGER DEFAULT 1, NTH
INTEGER DEFAULT 1) RETURNS INTEGER
SUBSTR(STR CLOB, AMOUNT INTEGER DEFAULT 32767, START_OFFSET
INTEGER DEFAULT 1) RETURNS VARCHAR2
SUBSTR(STR BLOB, AMOUNT INTEGER DEFAULT 32767, START_OFFSET
INTEGER DEFAULT 1) RETURNS RAW

```

```

GETLENGTH(STR CLOB) RETURNS INTEGER
GETLENGTH(STR BLOB) RETURNS INTEGER
APPEND(dest_lob BLOB,src_lob BLOB)/APPEND(CLOB,CLOB)
COMPARE(lob_1 BLOB,lob_2 BLOB,amount INT4 DEFAULT
2147483647,offset_1 INT4 DEFAULT 1,offset_2 INT4 DEFAULT 1)
RETURNS INTEGER
COMPARE(CLOB,CLOB,INT4 DEFAULT 2147483647,INT4 DEFAULT 1,INT4
DEFAULT 1) RETURNS INTEGER
COPY(dest_lob BLOB,src_lob BLOB,amount INT4,dest_offset INT4
DEFAULT 1,src_offset INT4 DEFAULT 1)/COPY(CLOB,CLOB,INT4,INT4
DEFAULT 1,INT4 DEFAULT 1)
ERASE(lob_loc BLOB,amount INT4,p_offset INT4 DEFAULT 1)/
ERASE(CLOB,INT4,INT4 DEFAULT 1)
READ(lob_loc BLOB,amount INT4,p_offset INT4,buffer RAW)/
READ(CLOB,INT4,INT4,TEXT)
TRIM(lob_loc BLOB,newlen INT4)/TRIM(CLOB,INT4)
WRITE(lob_loc BLOB,amount INT4,p_offset INT4,buffer RAW)/
WRITE(CLOB,INT4,INT4,TEXT)
WRITEAPPEND(lob_loc BLOB,amount INT4,buffer RAW)/
WRITEAPPEND(CLOB,INT4,TEXT)

```

## Features

### F.56.6.3.1. Description

This section explains each feature of DBMS\_LOB.

#### INSTR

- Offset of the start of the matched pattern, in bytes or characters.It returns 0 if the pattern is not found.
- It retruns null if any one or more of the IN parameters was NULL or INVALID.
- It returns NULL if offset < 1.

#### Example

```

select dbms_lob.INSTR('Thomas', 'om') from dual;
select dbms_lob.INSTR('Thomas'::blob,
utl_raw.CAST_TO_RAW('om')) from dual;

```

#### SUBSTR

- Extracts the substring of string starting at the start'th character if that is specified, and stopping after count characters if that is specified.
- It returns NULL if any input parameter is NULL
- It returns NULL if amount < 1.
- It returns NULL if offset < 1.

#### Example

```

select dbms_lob.substr('1234567',1,2) from dual;
select dbms_lob.substr('1234567'::blob,1,2) from dual;

```

**GETLENGTH**

- The length of the text in bytes or characters as an INTEGER.
- NULL is returned if the input str is NULL.

**Example**

```
select DBMS_LOB.GETLENGTH('abc') from dual;
```

**APPEND**

- Appends the contents of the source LOB to the destination LOB.

**Example**

```
declare
    l_blob          blob := 'abcd'::blob;
    l_clob          clob := 'abcd'::clob;
begin
    dbms_output.serveroutput(true);
    dbms_lob.append(l_blob, 'ext'::blob);
    dbms_output.put_line(l_blob::text);

    dbms_lob.append(l_clob, 'ext'::clob);
    dbms_output.put_line(l_clob);
end;
/
```

**COMPARE**

- Compares two entire LOBs or parts of two LOBs.
- Returns 0 if `lob\_1` equals `lob\_2`, -1 if `lob\_1` is less than `lob\_2`, 1 if `lob\_1` is greater than `lob\_2`.
- Returns NULL if any of amount, offset\_1 or offset\_2 is not a valid LOB offset value. A valid offset is within the range of 1 to LOBMAXSIZE inclusive.

**Example**

```
declare
    l_result        int;
    l_blob          blob := 'abcd'::blob;
    l_clob          clob := 'abcd'::clob;
    l_raw_result    raw;
    l_amout         INTEGER := 100;
    l_text_result   text;
begin
    dbms_output.serveroutput(true);
    l_result := dbms_lob.compare('abcd'::blob, 'abcd'::blob);
    dbms_output.put_line(l_result);
    l_result := dbms_lob.compare('abcd'::clob, 'abcd'::clob);
    dbms_output.put_line(l_result);

end;
```

/

**COPY**

- Copies all, or part, of the source LOB to the destination LOB. You can specify the offsets for both the source and destination LOBs, and the number of bytes or characters to copy.
- If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination BLOB or CLOB respectively. If the offset is less than the current length of the destination LOB, then existing data is overwritten.

**Example**

```
declare
    l_result          int;
    l_blob            blob := 'abcd'::blob;
    l_clob            clob := 'abcd'::clob;
    l_raw_result      raw;
    l_amout           INTEGER := 100;
    l_text_result     text;
begin
    dbms_output.serveroutput(true);
    dbms_lob.copy(l_blob, 'new_blob'::blob, 100);
    dbms_output.put_line(l_blob::text);
    dbms_lob.copy(l_blob, 'xnew_blob'::blob, 100, 1, 2);
    dbms_output.put_line(l_blob::text);
    dbms_lob.copy(l_blob, 'xnew_blob'::blob, 100, 2, 2);
    dbms_output.put_line(l_blob::text);
end;
/
```

**ERASE**

- Erases an entire internal LOB or part of an internal LOB.
- When data is erased from the middle of a LOB, zero-byte fillers or spaces are written for BLOBs or CLOBs respectively.
- The actual number of bytes or characters erased can differ from the number you specified in the amount parameter if the end of the LOB value is reached before erasing the specified number. The actual number of characters or bytes erased is returned in the amount parameter.

**Example**

```
declare
    l_result          int;
    l_blob            blob := 'abcd'::blob;
    l_clob            clob := 'abcd'::clob;
    l_raw_result      raw;
    l_amout           INTEGER := 100;
    l_text_result     text;
begin
    dbms_output.serveroutput(true);

    l_blob := 'abcd'::blob;
    l_amout := 100;
```

```
dbms_output.put_line(l_blob::text);
dbms_lob.erase(l_blob, l_amount);
dbms_output.put_line(l_blob::text);

l_clob := 'abcd'::clob;
l_amount := 4;
dbms_lob.erase(l_clob, l_amount);
dbms_output.put_line(l_clob);
end;
/
```

## READ

- This procedure reads a piece of a LOB, and returns the specified amount into the buffer parameter, starting from an absolute offset from the beginning of the LOB.
- The number of bytes or characters actually read is returned in the amount parameter. If the input offset points past the End of LOB, then amount is set to 0, and a NO\_DATA\_FOUND exception is raised.

## Example

```
declare
  l_result      int;
  l_blob        blob := 'abcd'::blob;
  l_clob        clob := 'abcd'::clob;
  l_raw_result  raw;
  l_amount      INTEGER := 100;
  l_text_result text;
begin
  dbms_output.serveroutput(true);

  l_amount := 5;
  dbms_lob.read('abcde'::blob, l_amount, 1, l_raw_result);
  dbms_output.put_line(l_raw_result);

  l_amount := 5;
  dbms_lob.read('abcde'::clob, l_amount, 1, l_text_result);
  dbms_output.put_line(l_text_result);
end;
/
```

## TRIM

- This procedure trims the value of the internal LOB to the length you specify in the newlen parameter. Specify the length in bytes for BLOBs, and specify the length in characters for CLOBs.

## Example

```
declare
  l_result      int;
  l_blob        blob := 'abcd'::blob;
  l_clob        clob := 'abcd'::clob;
  l_raw_result  raw;
  l_amount      INTEGER := 100;
  l_text_result text;
```

```
begin
  dbms_output.serveroutput(true);

  l_blob := 'abcde'::blob;
  dbms_lob.trim(l_blob, 1);
  dbms_output.put_line(l_blob::text);

  l_clob := 'abcde'::clob;
  dbms_lob.trim(l_clob, 1);
  dbms_output.put_line(l_clob);
end;
/
```

## WRITE

- This procedure writes a specified amount of data into an internal LOB, starting from an absolute offset from the beginning of the LOB. The data is written from the buffer parameter.
- WRITE replaces (overwrites) any data that already exists in the LOB at the offset, for the length you specify.

### Example

```
declare
  l_result      int;
  l_blob        blob := 'abcd'::blob;
  l_clob        clob := 'abcd'::clob;
  l_raw_result  raw;
  l_amout       INTEGER := 100;
  l_text_result text;
begin
  dbms_output.serveroutput(true);

  l_blob := 'abcde'::blob;
  dbms_lob.write(l_blob, pg_catalog.length(utl_raw.CAST_TO_RAW('#
#')), 2, utl_raw.CAST_TO_RAW('##'));
  dbms_output.put_line(l_blob::text);

  -- write clob
  l_clob := 'abcde'::clob;
  dbms_lob.write(l_clob, 2, 2, '##'::text);
  dbms_output.put_line(l_clob);
end;
/
```

## WRITEAPPEND

- This procedure writes a specified amount of data to the end of an internal LOB. The data is written from the buffer parameter.

### Example

```
declare
  l_result      int;
  l_blob        blob := 'abcd'::blob;
  l_clob        clob := 'abcd'::clob;
```

```

l_raw_result    raw;
l_amout        INTEGER := 100;
l_text_result  text;
begin
  dbms_output.serveroutput(true);

  -- writeappend blob
  l_blob := 'abcde'::blob;
  dbms_lob.writeappend(l_blob,
pg_catalog.length(utl_raw.CAST_TO_RAW('##')),
utl_raw.CAST_TO_RAW('##'));
  dbms_output.put_line(l_blob::text);

  -- write clob
  l_clob := 'abcde'::clob;
  dbms_lob.writeappend(l_clob, 2,'##'::text);
  dbms_output.put_line(l_clob);
end;
/

```

### F.56.6.3.2. Usage Example

A usage example of DBMS\_LOB is shown below.

```

CREATE PROCEDURE dbms_lob_exe() AS $$
DECLARE
  str1 text;
  str2 text;
  pos INTEGER;
  count INTEGER;
BEGIN
  str2 := dbms_lob.substr('1234567',2,3);
  pos := dbms_lob.instr('Tech on the net', 'e');
  count := dbms_lob.getlength('1234567');
  raise info 'str2=%,pos=%,count=%', str2, pos, count;
END;
$$ LANGUAGE plpgsql;
call dbms_lob_exe();
DROP PROCEDURE dbms_lob_exe();

```

### F.56.6.4. DBMS\_OUTPUT

#### Overview

Sends messages to clients such as ltsql from PL/pgSQL.

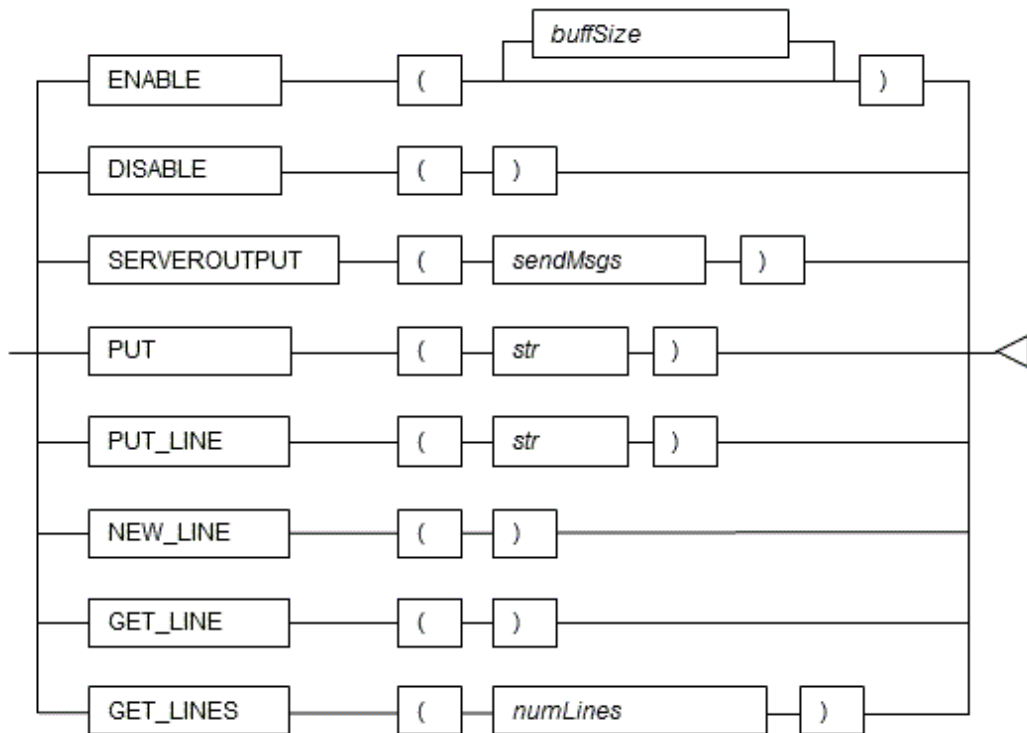

#### Features

**Table F.121. DBMS\_OUTPUT Features**

Feature	Description
ENABLE	Enables features of this package.
DISABLE	Disables features of this package.
SERVEROUTPUT	Controls whether messages are sent.

Feature	Description
PUT	Sends messages.
PUT_LINE	Sends messages with a newline character appended.
NEW_LINE	Sends a newline character. It cannot be used with parameters, Supports two usages: <code>dbms_output.new_line</code> and <code>dbms_output.new_line()</code> .
GET_LINE	Retrieves a line from the message buffer.
GET_LINES	Retrieves multiple lines from the message buffer.

**Syntax**

**F.56.6.4.1. Description**

This section explains each feature of DBMS\_OUTPUT.

**ENABLE**

- ENABLE enables the use of PUT, PUT\_LINE, NEW\_LINE, GET\_LINE, and GET\_LINES.
- With multiple executions of ENABLE, the value specified last is the buffer size (in bytes). Specify a buffer size from 2000 to 1000000.
- The default value of the buffer size is 20000. If NULL is specified as the buffer size, 1000000 will be used.
- If ENABLE has not been executed, PUT, PUT\_LINE, NEW\_LINE, GET\_LINE, and GET\_LINES are ignored even if they are executed.

**Example**

```
PERFORM DBMS_OUTPUT.ENABLE(20000);
```

### **DISABLE**

- DISABLE disables the use of PUT, PUT\_LINE, NEW\_LINE, GET\_LINE, and GET\_LINES.
- Remaining buffer information is discarded.

### **Example**

```
PERFORM DBMS_OUTPUT.DISABLE();
```

### **SERVEROUTPUT**

- SERVEROUTPUT controls whether messages are sent.
- Specify TRUE or FALSE for *sendMsgs*.
- If TRUE is specified, when PUT, PUT\_LINE, or NEW\_LINE is executed, the message is sent to a client such as ltsql and not stored in the buffer.
- If FALSE is specified, when PUT, PUT\_LINE, or NEW\_LINE is executed, the message is stored in the buffer and not sent to a client such as ltsql.

### **See**

Refer to "The SQL Language" > "Data Types" > "Boolean Type" in the LightDB Documentation for information on boolean type (TRUE/FALSE) values.

### **Example**

```
PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);
```

### **PUT**

- PUT sets the message to be sent.
- The string is the message to be sent.
- When TRUE is specified for SERVEROUTPUT, the messages are sent to clients such as ltsql.
- When FALSE is specified for SERVEROUTPUT, the messages are retained in the buffer.
- PUT does not append a newline character. To append a newline character, execute NEW\_LINE.
- If a string longer than the buffer size specified in ENABLE is sent, an error occurs.

### **Example**

```
PERFORM DBMS_OUTPUT.PUT('abc');
```

### **PUT\_LINE**

- PUT\_LINE sets the message to be sent appended with a newline character.

- The string is the message to be sent.
- When TRUE is specified for SERVEROUTPUT, the messages are sent to clients such as ltsql.
- When FALSE is specified for SERVEROUTPUT, the messages are retained in the buffer.
- If a string longer than the buffer size specified in ENABLE is sent, an error occurs.

**Example**

```
PERFORM DBMS_OUTPUT.PUT_LINE( ' abc ' );
```

**NEW\_LINE**

- NEW\_LINE appends a newline character to the message created with PUT.
- When TRUE is specified for SERVEROUTPUT, the messages are sent to clients such as ltsql.
- When FALSE is specified for SERVEROUTPUT, the messages are retained in the buffer.

**Example**

```
PERFORM DBMS_OUTPUT.NEW_LINE( ) ;
```

**GET\_LINE**

- GET\_LINE retrieves a line from the message buffer.
- Use a SELECT statement to obtain the retrieved line and status code returned by the operation, which are stored in the line and status columns.
- The line column stores the line retrieved from the buffer. The data type of line is TEXT.
- The status column stores the status code returned by the operation: 0-completed successfully; 1-failed because there are no more lines in the buffer. The data type of status is INTEGER.
- If GET\_LINE or GET\_LINES is executed and then PUT, PUT\_LINE or PUT\_LINES is executed while messages that have not been retrieved from the buffer still exist, the messages not retrieved from the buffer will be discarded.

**Example**

```
DECLARE
    buff1  VARCHAR( 20 );
    stts1  INTEGER;
BEGIN
    SELECT line,status INTO buff1,stts1 FROM
DBMS_OUTPUT.GET_LINE( ) ;
```

**GET\_LINES**

- GET\_LINES retrieves multiple lines from the message buffer.
- Specify the number of lines to retrieve from the buffer.
- Use a SELECT statement to obtain the retrieved lines and the number of lines retrieved, which are stored in the lines and numlines columns.

- The lines column stores the lines retrieved from the buffer. The data type of lines is TEXT.
- The numlines column stores the number of lines retrieved from the buffer. If this number is less than the number of lines requested, then there are no more lines in the buffer. The data type of numlines is INTEGER.
- If GET\_LINE or GET\_LINES is executed and then PUT, PUT\_LINE, or NEW\_LINE is executed while messages that have not been retrieved from the buffer still exist, the messages not retrieved from the buffer will be discarded.

**Example**

```
DECLARE
    buff    VARCHAR(20)[10];
    stts    INTEGER := 10;
BEGIN
    SELECT lines, numlines INTO buff,stts FROM
DBMS_OUTPUT.GET_LINES(stts);
```

**F.56.6.4.2. Usage Example**

A usage example of DBMS\_OUTPUT is shown below.

```
CREATE FUNCTION dbms_output_exe() RETURNS VOID AS $$
DECLARE
    buff1 VARCHAR(20);
    buff2 VARCHAR(20);
    stts1 INTEGER;
    stts2 INTEGER;
BEGIN
    PERFORM DBMS_OUTPUT.DISABLE();
    PERFORM DBMS_OUTPUT.ENABLE();
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(FALSE);
    PERFORM DBMS_OUTPUT.PUT('DBMS_OUTPUT TEST 1');
    PERFORM DBMS_OUTPUT.NEW_LINE();
    PERFORM DBMS_OUTPUT.PUT_LINE('DBMS_OUTPUT TEST 2');
    SELECT line,status INTO buff1,stts1 FROM
DBMS_OUTPUT.GET_LINE();
    SELECT line,status INTO buff2,stts2 FROM
DBMS_OUTPUT.GET_LINE();
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);
    PERFORM DBMS_OUTPUT.PUT_LINE(buff1);
    PERFORM DBMS_OUTPUT.PUT_LINE(buff2);
END;
$$ LANGUAGE plpgsql;
SELECT dbms_output_exe();
DROP FUNCTION dbms_output_exe();
```

**F.56.6.5. DBMS\_PIPE****Overview**

Performs communication between sessions that execute PL/pgSQL.

This package can be used for 1:1 communication, such as when data is being exchanged between sessions executing PL/pgSQL.

For pipes, there are explicit pipes and implicit pipes, and furthermore, for explicit pipes, you can select public pipes and private pipes. The characteristics of each type are as follows:

### Types of pipes

**Table F.122. Types of pipes**

Type	Characteristics
Explicit pipe	<ul style="list-style-type: none"> <li>- CREATE_PIPE is used to create a pipe explicitly.</li> <li>- While creating a pipe, you can select between a public pipe and private pipe.</li> <li>- It is necessary to use REMOVE_PIPE to explicitly remove a pipe.</li> </ul>
Implicit pipe	<ul style="list-style-type: none"> <li>- Created automatically when SEND_MESSAGE and RECEIVE_MESSAGE are used.</li> <li>- The pipe that is created becomes a public pipe.</li> <li>- When messages are received using RECEIVE_MESSAGE, if there are no additional messages remaining in the pipe, the pipe will be removed automatically.</li> </ul>
Public pipe	<ul style="list-style-type: none"> <li>- Can be created as an explicit pipe or implicit pipe.</li> <li>- Can also be used by users other than the creator.</li> </ul>
Private pipe	<ul style="list-style-type: none"> <li>- Can only be created as an explicit pipe.</li> <li>- Can only be used by its creator.</li> </ul>

### Note

- Up to 50 pipes can be used concurrently by a single instance.
- In cases where pipes are frequently created and removed repetitively, use public pipes. If you create a private pipe, internal information (the creator of the private pipe) will remain even after the pipe is removed. Thus, repeatedly creating and removing pipes may ultimately cause memory to run out.
- If a timeout occurs without receiving a message when an implicit pipe is created by RECEIVE\_MESSAGE, the pipe will not be removed.

### Features

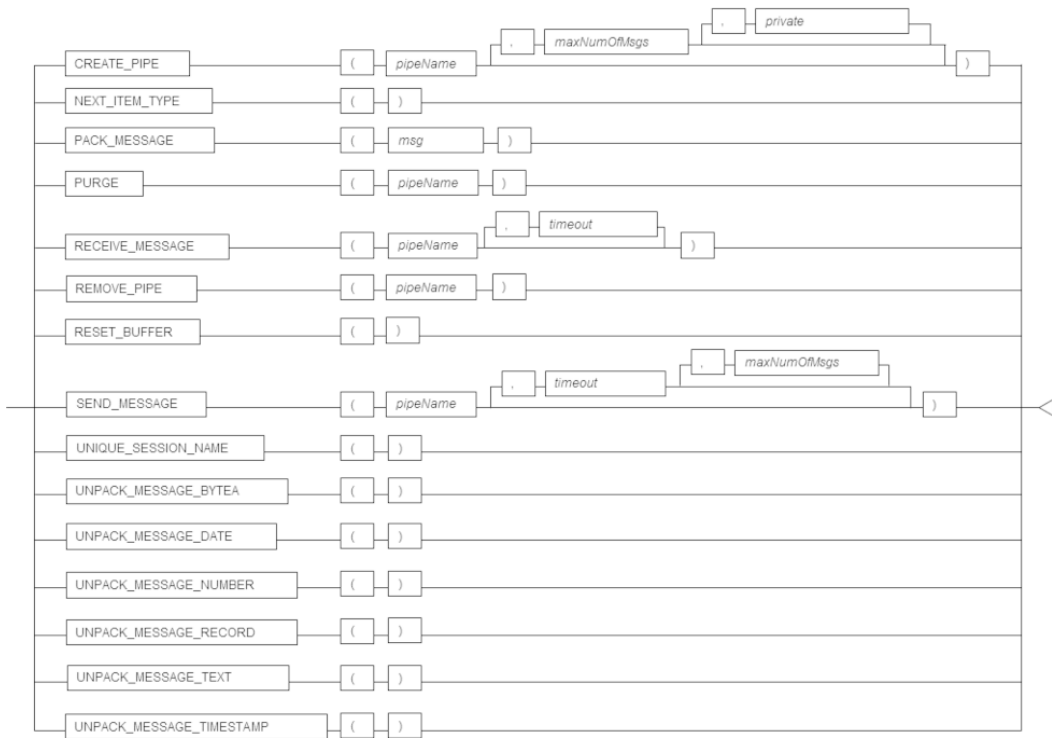

**Table F.123. DBMS\_PIPE Features**

Feature	Description
CREATE_PIPE	Creates a public or private pipe.
NEXT_ITEM_TYPE	Determines the data type of the next item in the local buffer, and returns that type.
PACK_MESSAGE	Sets a message in the local buffer.
PURGE	Empties the contents of the specified pipe.
RECEIVE_MESSAGE	Sets a received message in the local buffer.

Feature	Description
REMOVE_PIPE	Removes the specified pipe.
RESET_BUFFER	Resets the set position of the local buffer.
SEND_MESSAGE	Sends the contents of the local buffer.
UNIQUE_SESSION_NAME	Returns a unique session name.
UNPACK_MESSAGE_BYTEA	Receives a message in the local buffer in BYTEA type.
UNPACK_MESSAGE_DATE	Receives a message in the local buffer in DATE type.
UNPACK_MESSAGE_NUMBER	Receives a message in the local buffer in NUMERIC type.
UNPACK_MESSAGE_RECORD	Receives a message in the local buffer in RECORD type.
UNPACK_MESSAGE_TEXT	Receives a message in the local buffer in TEXT type.
UNPACK_MESSAGE_TIMESTAMP	Receives a message in the local buffer in TIMESTAMP type.

**Syntax**

**F.56.6.5.1. Description of Features**

This section explains each feature of DBMS\_PIPE.

**CREATE\_PIPE**

- CREATE\_PIPE explicitly creates a pipe environment for data communication.
- Specify the name of the pipe to be created.
- Pipe names are case-sensitive.

- Specify the maximum number of messages that can be sent or received. If omitted, 0 (cannot send messages) will be used. Specify from 1 to 32767.
- Specify TRUE or FALSE for *private*. If TRUE is specified, a private pipe will be created. If FALSE is specified, a public pipe will be created. The default is FALSE.
- An error will occur if a pipe of the same name has already been created.

**See**

Refer to "The SQL Language" > "Data Types" > "Boolean Type" in the LightDB Documentation for information on boolean type (TRUE/FALSE) values.

**Example**

```
PERFORM DBMS_PIPE.CREATE_PIPE('P01', 100, FALSE);
```

**NEXT\_ITEM\_TYPE**

- NEXT\_ITEM\_TYPE returns the next data type in the local buffer.
- The data type of the return value is INTEGER. One of the following values is returned:

**Table F.124. Values returned by NEXT\_ITEM\_TYPE**

Return value	Data type
9	NUMERIC type
11	TEXT type
12	DATE type
13	TIMESTAMP type
23	BYTEA type
24	RECORD type
0	No data in the buffer

**Example**

```
DECLARE
    i_iType    INTEGER;
BEGIN
    i_iType := DBMS_PIPE.NEXT_ITEM_TYPE();
```

**PACK\_MESSAGE**

- PACK\_MESSAGE sets the specified message in the local buffer.
- Specify the data to be set in the local buffer. The following data types can be used:
  - Character type (\*1)
  - Integer type (\*2)
  - NUMERIC type
  - DATE type

- TIMESTAMP type (\*3)
- BYTEA type
- RECORD type

\*1: The character type is converted internally to TEXT type.

\*2: The integer type is converted internally to NUMERIC type.

\*3: The TIMESTAMP type is converted internally to TIMESTAMP WITH TIME ZONE type.

- Each time PACK\_MESSAGE is called, a new message is added to the local buffer.
- The size of the local buffer is approximately 8 KB. However, each message has overhead, so the total size that can be stored is actually less than 8 KB. To clear the local buffer, send a message (SEND\_MESSAGE), or reset the buffer (RESET\_BUFFER) to its initial state.

### Example

```
PERFORM DBMS_PIPE.PACK_MESSAGE('Message Test001');
```

### PURGE

- PURGE removes the messages in the pipe.
- Specify the name of the pipe for which the messages are to be removed.
- Pipe names are case-sensitive.

### Example

```
PERFORM DBMS_PIPE.PURGE('P01');
```

### Note

When PURGE is executed, the local buffer is used to remove the messages in the pipe. Therefore, if there are any messages remaining in the pipe, the local buffer will be overwritten by PURGE.

### RECEIVE\_MESSAGE

- RECEIVE\_MESSAGE receives messages that exist in the specified pipe, and sets those messages in the local buffer.
- Messages are received in the units in which they are sent to the pipe by SEND\_MESSAGE. Received messages are removed from the pipe after being set in the local buffer.
- Specify the name of the pipe for which the messages are to be received.
- Pipe names are case-sensitive.
- Specify the maximum wait time *timeout* in seconds to wait for a message. If omitted, the default is 31536000 seconds (1 year).
- The data type of the return value is INTEGER. If a message is received successfully, 0 is returned. If a timeout occurs, 1 is returned.

**Example**

```
DECLARE
    i_Ret    INTEGER;
BEGIN
    i_Ret := DBMS_PIPE.RECEIVE_MESSAGE('P01', 60);
```

**REMOVE\_PIPE**

- REMOVE\_PIPE removes the specified pipe.
- Specify the name of the pipe to be removed.
- Pipe names are case-sensitive.

**Example**

```
PERFORM DBMS_PIPE.REMOVE_PIPE('P01');
```

**RESET\_BUFFER**

- RESET\_BUFFER resets the set position of the local buffer. Any unnecessary data remaining in the local buffer can be discarded using this operation.

**Example**

```
PERFORM DBMS_PIPE.RESET_BUFFER();
```

**SEND\_MESSAGE**

- SEND\_MESSAGE sends data stored in the local buffer to the specified pipe.
- Specify the name of the pipe that the data is to be sent to.
- Pipe names are case-sensitive.
- Specify the maximum wait time *timeout* in seconds for sending data stored in the local buffer. If omitted, the default is 31536000 seconds (1 year).
- Specify the maximum number of messages that can be sent or received. If omitted, the maximum number of messages set in CREATE\_PIPE is used. If omitted in the implicit pipe, the number of messages will be unlimited. Specify from 1 to 32767.
- If the maximum number of messages is specified in both SEND\_MESSAGE and CREATE\_PIPE, the larger of the values will be used.
- The data type of the return value is INTEGER. If a message is received successfully, 0 is returned. If a timeout occurs, 1 is returned.

**Example**

```
DECLARE
    i_Ret    INTEGER;
BEGIN
```

```
i_Ret := DBMS_PIPE.SEND_MESSAGE('P01', 10, 20);
```

### Note

A timeout will occur during sending if the maximum number of messages is reached, or if the message being sent is too large. If a timeout occurs, use `RECEIVE_MESSAGE` to receive any messages that are in the pipe.

### UNIQUE\_SESSION\_NAME

- `UNIQUE_SESSION_NAME` returns a name that is unique among all the sessions. This name can be used as the pipe name.
- Multiple calls from the same session always return the same name.
- The data type of the return value is `VARCHAR`. Returns a string of up to 30 characters.

### Example

```
DECLARE
    p_Name    VARCHAR(30);
BEGIN
    p_Name := DBMS_PIPE.UNIQUE_SESSION_NAME();
```

### UNPACK\_MESSAGE\_BYTEA

- `UNPACK_MESSAGE_BYTEA` receives `BYTEA` type messages in the local buffer.
- Messages are received in the unit set in the local buffer by `PACK_MESSAGE`. Received messages are removed from the local buffer.
- The data type of the return value is `BYTEA`.
- If no messages exist in the local buffer, a `NULL` value is returned.
- For the data type, it is necessary to align with the data type set by `PACK_MESSAGE`. If the data type is different, the following error will occur.

```
ERROR: datatype mismatch
DETAIL:  unpack unexpected type: xx
```

### Example

```
DECLARE
    g_Bytea   BYTEA;
BEGIN
    g_Bytea := DBMS_PIPE.UNPACK_MESSAGE_BYTEA();
```

### UNPACK\_MESSAGE\_DATE

- `UNPACK_MESSAGE_DATE` receives `DATE` type messages in the local buffer.
- Messages are received in the unit set in the local buffer by `PACK_MESSAGE`. Received messages are removed from the local buffer.

- The data type of the return value is DATE.
- If no messages exist in the local buffer, a NULL value is returned.
- For the data type, it is necessary to align with the data type set by PACK\_MESSAGE. If the data type is different, the following error will occur.

```
ERROR: datatype mismatch
DETAIL: unpack unexpected type: xx
```

### Example

```
DECLARE
    g_Date    DATE;
BEGIN
    g_Date := DBMS_PIPE.UNPACK_MESSAGE_DATE();
```

### Note

If the "oracle" schema is set in search\_path, the DATE type of oracle will be used, so for receiving data, use UNPACK\_MESSAGE\_TIMESTAMP. UNPACK\_MESSAGE\_DATE is the interface for the DATE type of LightDB.

### UNPACK\_MESSAGE\_NUMBER

- UNPACK\_MESSAGE\_NUMBER receives NUMERIC type messages in the local buffer.
- Messages are received in the unit set in the local buffer by PACK\_MESSAGE. Received messages are removed from the local buffer.
- The data type of the return value is NUMERIC.
- If no messages exist in the local buffer, a NULL value is returned.
- For the data type, it is necessary to align with the data type set by PACK\_MESSAGE. If the data type is different, the following error will occur.

```
ERROR: datatype mismatch
DETAIL: unpack unexpected type: xx
```

### Example

```
DECLARE
    g_Number    NUMERIC;
BEGIN
    g_Number := DBMS_PIPE.UNPACK_MESSAGE_NUMBER();
```

### UNPACK\_MESSAGE\_RECORD

- UNPACK\_MESSAGE\_RECORD receives RECORD type messages in the local buffer.
- Messages are received in the unit set in the local buffer by PACK\_MESSAGE. Received messages are removed from the local buffer.

- The data type of the return value is RECORD.
- If no messages exist in the local buffer, a NULL value is returned.
- For the data type, it is necessary to align with the data type set by PACK\_MESSAGE. If the data type is different, the following error will occur.

```
ERROR: datatype mismatch
DETAIL: unpack unexpected type: xx
```

### Example

```
DECLARE
    msg1      TEXT;
    status    NUMERIC;
BEGIN
    SELECT col1, col2 INTO msg1, status FROM
DBMS_PIPE.UNPACK_MESSAGE_RECORD();
```

### UNPACK\_MESSAGE\_TEXT

- UNPACK\_MESSAGE\_TEXT receives TEXT type messages in the local buffer.
- Messages are received in the unit set in the local buffer by PACK\_MESSAGE. Received messages are removed from the local buffer.
- The data type of the return value is TEXT.
- If no messages exist in the local buffer, a NULL value is returned.
- For the data type, it is necessary to align with the data type set by PACK\_MESSAGE. If the data type is different, the following error will occur.

```
ERROR: datatype mismatch
DETAIL: unpack unexpected type: xx
```

### Example

```
DECLARE
    g_Text    TEXT;
BEGIN
    g_Text := DBMS_PIPE.UNPACK_MESSAGE_TEXT();
```

### UNPACK\_MESSAGE\_TIMESTAMP

- UNPACK\_MESSAGE\_TIMESTAMP receives TIMESTAMP WITH TIME ZONE type messages in the local buffer.
- Messages are received in the unit set in the local buffer by PACK\_MESSAGE. Received messages are removed from the local buffer.
- The data type of the return value is TIMESTAMP WITH TIME ZONE.

- If no messages exist in the local buffer, a NULL value is returned.
- For the data type, it is necessary to align with the data type set by PACK\_MESSAGE. If the data type is different, the following error will occur.

```
ERROR: datatype mismatch
DETAIL: unpack unexpected type: xx
```

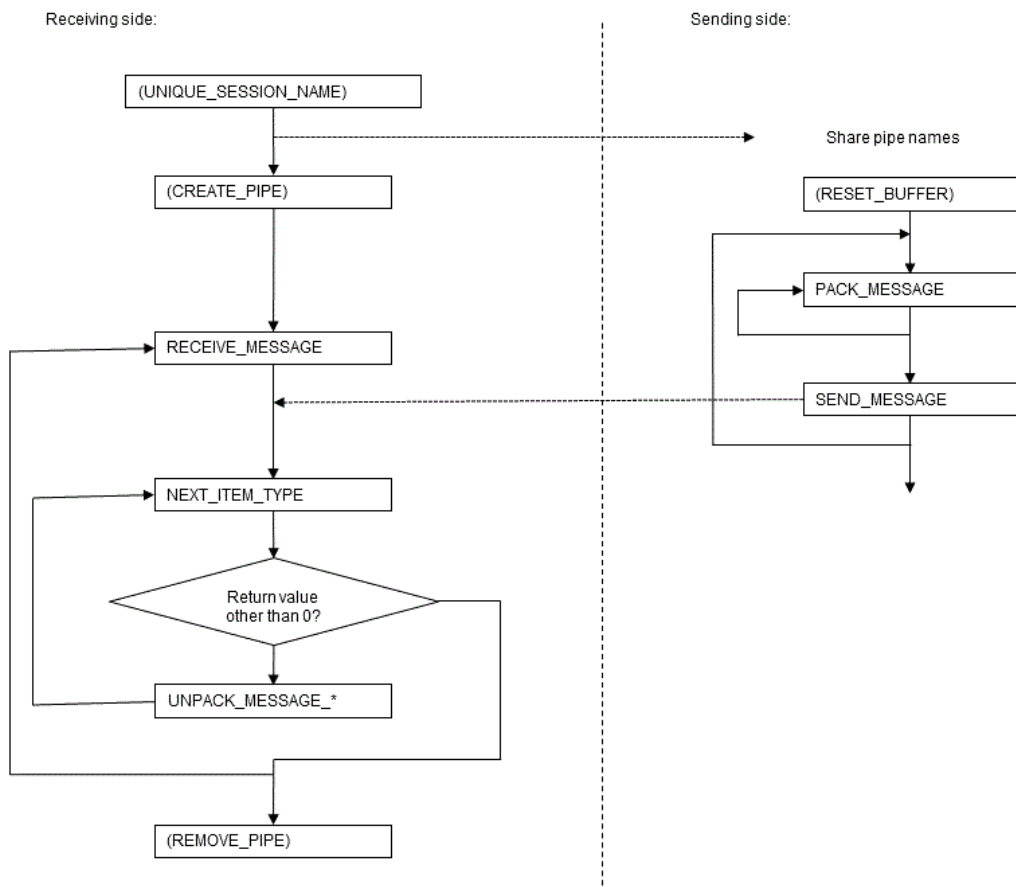

**Example**

```
DECLARE
    g_Timestampz    TIMESTAMP WITH TIME ZONE;
BEGIN
    g_Timestampz := DBMS_PIPE.UNPACK_MESSAGE_TIMESTAMP();
```

**F.56.6.5.2. Usage Example**

Below is a usage example of the processing flow of DBMS\_PIPE.

**Flow of DBMS\_PIPE**

**Note**

- When CREATE\_PIPE is used to explicitly create a pipe, ensure to use REMOVE\_PIPE to remove the pipe. If a pipe is not removed explicitly, once created, it will remain until the instance is stopped.

- In the flow diagram, CREATE\_PIPE and REMOVE\_PIPE are described on the receiving side, however, these can be executed on the sending side. In order to maintain consistency, it is recommended to create and remove pipes on one side.
- An error will occur for CREATE\_PIPE if a pipe of the same name already exists. Implicitly created pipes are also the target of SEND\_MESSAGE and RECEIVE\_MESSAGE, so when executing CREATE\_PIPE, ensure that SEND\_MESSAGE and RECEIVE\_MESSAGE are not called beforehand.
- DBMS\_ALERT and DBMS\_PIPE use the same memory environment. Therefore, when insufficient memory is detected for DBMS\_ALERT, it is possible that insufficient memory will also be detected for DBMS\_PIPE.

### Information

The information of pipes that are in use can be viewed in the DBMS\_PIPE.DB\_PIPES view.

```
SELECT * from dbms_pipe.db_pipes;
name | items | size | limit | private | owner
-----+-----+-----+-----+-----+-----
P01  |      1 |   18 |   100 | f        |
(1 row)
```

### Usage example

- Sending side

```
CREATE FUNCTION send_dbms_pipe_exe(IN pipe_mess text) RETURNS
void AS $$
DECLARE
    pipe_name text := 'sample_pipe';
    pipe_time timestamp := current_timestamp;
    pipe_stat int;
BEGIN
    PERFORM DBMS_PIPE.RESET_BUFFER();
    PERFORM DBMS_PIPE.PACK_MESSAGE(pipe_mess);
    PERFORM DBMS_PIPE.PACK_MESSAGE(pipe_time);
    pipe_stat := DBMS_PIPE.SEND_MESSAGE(pipe_name);
    RAISE NOTICE 'PIPE_NAME: % SEND Return Value =%', pipe_name,
pipe_stat;
END;
$$ LANGUAGE plpgsql;

SELECT send_dbms_pipe_exe('Sample Message.');
```

- Receiving side

```
CREATE FUNCTION receive_dbms_pipe_exe() RETURNS void AS $$
DECLARE
    pipe_name text := 'sample_pipe';
    pipe_text text;
    pipe_num numeric;
    pipe_date date;
```

```

pipe_time timestamp with time zone;
pipe_byte bytea;
pipe_reco record;
pipe_item int;
pipe_stat int;
BEGIN
pipe_stat := DBMS_PIPE.RECEIVE_MESSAGE(pipe_name,300);
RAISE NOTICE 'Return Value = %', pipe_stat;
    LOOP
pipe_item := DBMS_PIPE.NEXT_ITEM_TYPE();
RAISE NOTICE 'Next Item : %', pipe_item;
IF (pipe_item = 9) THEN
pipe_num := DBMS_PIPE.UNPACK_MESSAGE_NUMBER();
RAISE NOTICE 'Get Message : %' ,pipe_num;
ELSIF (pipe_item =11) THEN
pipe_text := DBMS_PIPE.UNPACK_MESSAGE_TEXT();
RAISE NOTICE 'Get Message : %' ,pipe_text;
ELSIF (pipe_item = 12) THEN
pipe_date := DBMS_PIPE.UNPACK_MESSAGE_DATE();
RAISE NOTICE 'Get Message : %' ,pipe_date;
ELSIF (pipe_item = 13) THEN
pipe_time := DBMS_PIPE.UNPACK_MESSAGE_TIMESTAMP();
RAISE NOTICE 'Get Message : %' ,pipe_time;
ELSIF (pipe_item = 23) THEN
pipe_byte := DBMS_PIPE.UNPACK_MESSAGE_BYTEA();
RAISE NOTICE 'Get Message : %' ,pipe_byte;
ELSIF (pipe_item = 24) THEN
pipe_reco := DBMS_PIPE.UNPACK_MESSAGE_RECORD();
RAISE NOTICE 'Get Message : %' ,pipe_reco;
ELSE
EXIT;
END IF;
END LOOP;
PERFORM DBMS_PIPE.REMOVE_PIPE(pipe_name);
END;
$$ LANGUAGE plpgsql;

SELECT receive_dbms_pipe_exe();
DROP FUNCTION receive_dbms_pipe_exe();

```

## F.56.6.6. DBMS\_RANDOM

### Overview

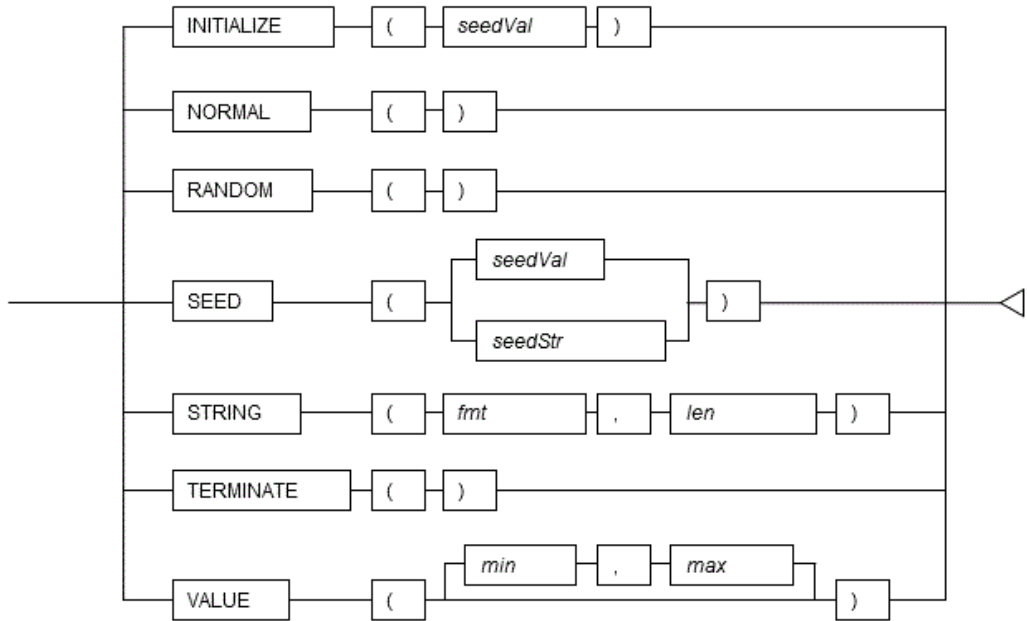

Generates random numbers in PL/pgSQL.

**Table F.125. DBMS\_RANDOM Features**

Feature	Description
INITIALIZE	Initializes the generation of random numbers.
NORMAL	Returns a normally distributed random number.
RANDOM	Generates a random number.
SEED	Resets the seed value.
STRING	Generates a random string.
TERMINATE	Terminates generation of random numbers.

Feature	Description
VALUE	Generates a random decimal number between 0 and 1, or between specified values.

**Syntax**

**F.56.6.6.1. Description of Features**

This section explains each feature of DBMS\_RANDOM.

**INITIALIZE**

- INITIALIZE initializes the generation of random numbers using the specified seed value.
- For *seedVal*, specify a SMALLINT or INTEGER type.

**Example**

```
PERFORM DBMS_RANDOM.INITIALIZE(999);
```

**NORMAL**

- NORMAL generates and returns a normally distributed random number.
- The return value type is DOUBLE PRECISION.

**Example**

```
DECLARE
  d_RunNum DOUBLE PRECISION;
BEGIN
  d_RunNum := DBMS_RANDOM.NORMAL();
```

## RANDOM

- RANDOM generates and returns a random number.
- The data type of the return value is INTEGER.

### Example

```

DECLARE
    d_RunInt    INTEGER;
BEGIN
    d_RunInt := DBMS_RANDOM.RANDOM();

```

## SEED

- SEED initializes the generation of a random number using the specified seed value or seed string.
- For *seedVal*, specify a SMALLINT or INTEGER type.
- Any string can be specified for the seed string.

### Example

```

PERFORM DBMS_RANDOM.SEED( '123' );

```

## STRING

- STRING generates and returns a random string in accordance with the specified display format and string length.
- For the display format *fmt*, specify any of the following values. An error will occur if any other value is specified.

**Table F.126. Values that can be specified for the display format**

Setting value	Generated string
'u', 'U'	Uppercase letters only
'l', 'L'	Lowercase letters only
'a', 'A'	Mixture of uppercase and lowercase letters
'x', 'X'	Uppercase letters and numbers
'p', 'P'	Any displayable character

- Specify the length of the string to be generated. Specify a SMALLINT or INTEGER type.
- The data type of the return value is TEXT.

### Example

```

DECLARE
    d_RunStr    TEXT;
BEGIN
    d_RunStr := DBMS_RANDOM.STRING( 'a', 20 );

```

**TERMINATE**

- Call TERMINATE to terminate generation of random numbers.

**Information**

TERMINATE does not do anything, but has been included for compatibility with Oracle databases.

**Example**

```
PERFORM DBMS_RANDOM.TERMINATE();
```

**VALUE**

- VALUE generates and returns a random number within the specified range.
- For *min* and *max*, specify a numeric data type. A random number between and inclusive of the minimum value and maximum value is generated.
- If the minimum value and maximum value are omitted, a random decimal number between 0 and 1 will be generated.
- The data type of the return value is DOUBLE PRECISION.

**Example**

```
DECLARE
    d_RunDb1    DOUBLE PRECISION;
BEGIN
    d_RunDb1 := DBMS_RANDOM.VALUE();
```

**F.56.6.6.2. Usage Example**

A usage example of DBMS\_RANDOM is shown below.

```
CREATE FUNCTION dbms_random_exe() RETURNS VOID AS $$
DECLARE
    w_rkey VARCHAR(10) := 'rnd111';
    i_rkey INTEGER := 97310;
BEGIN
    PERFORM DBMS_RANDOM.INITIALIZE(i_rkey);
    RAISE NOTICE 'RANDOM -> NORMAL : %', DBMS_RANDOM.NORMAL();
    RAISE NOTICE 'RANDOM -> RANDOM : %', DBMS_RANDOM.RANDOM();
    RAISE NOTICE 'RANDOM -> STRING : %',
DBMS_RANDOM.STRING('a',10);
    RAISE NOTICE 'RANDOM -> VALUE : %', DBMS_RANDOM.VALUE();
    PERFORM DBMS_RANDOM.SEED(w_rkey);
    RAISE NOTICE 'RANDOM -> NORMAL : %', DBMS_RANDOM.NORMAL();
    RAISE NOTICE 'RANDOM -> RANDOM : %', DBMS_RANDOM.RANDOM();
    RAISE NOTICE 'RANDOM -> STRING : %',
DBMS_RANDOM.STRING('p',10);
    RAISE NOTICE 'RANDOM -> VALUE : %',
DBMS_RANDOM.VALUE(1,100);
    PERFORM DBMS_RANDOM.TERMINATE();
END;
$$ LANGUAGE plpgsql;
```

```
SELECT dbms_random_exe();
DROP FUNCTION dbms_random_exe();
```

## F.56.6.7. DBMS\_UTILITY

### Overview

Provides utilities of PL/pgSQL.

**Table F.127. DBMS\_UTILITY Features**

Feature	Description
FORMAT_CALL_STACK	Returns the current call stack.
GET_HASH_VALUE	A hash value based on the input string.
CANONICALIZE	Canonicalizes a given string.
COMMA_TO_TABLE	Converts a comma-delimited list of names into a PL/SQL table of names.
TABLE_TO_COMMA	Converts a PL/SQL table of names into a comma-delimited list of names.
DB_VERSION	Returns version information for the database.
EXEC_DDL_STATEMENT	Executes the DDL statement in parse_string.
GET_TIME	Finds out the current time in hundredths of a second.

### Syntax

```
FORMAT_CALL_STACK(fmt text);
FORMAT_CALL_STACK();
GET_HASH_VALUE(name VARCHAR2,base INTEGER,hash_size INTEGER)
CANONICALIZE(name TEXT,canon_name TEXT,canon_len INT4)
COMMA_TO_TABLE(list TEXT,tablen INT4,tab TEXT[])
TABLE_TO_COMMA(tab TEXT[],tablen INT4,list TEXT)
DB_VERSION(version TEXT,compatibility TEXT)
EXEC_DDL_STATEMENT(parse_string TEXT)
```

### F.56.6.7.1. Description of Features

This section explains each feature of DBMS\_UTILITY.

#### FORMAT\_CALL\_STACK

- FORMAT\_CALL\_STACK returns the current call stack of PL/pgSQL.
- For the display format `fmt`, specify any of the following values. An error will occur if any other value is specified.

**Table F.128. Values that can be specified for the display format**

Setting value	Displayed content
'o'	Standard-format call stack display (with header)
's'	Standard-format call stack display (without header)

Setting value	Displayed content
'p'	Comma-delimited call stack display (without header)

- If the display format is omitted, display format 'o' will be used.
- The data type of the return value is TEXT.

**Example**

```

DECLARE
    s_StackTrace    TEXT
BEGIN
    s_StackTrace := DBMS_UTILITY.FORMAT_CALL_STACK();

```

**Note**

If a locale other than English is specified for the message locale, the call stack result may not be retrieved correctly. To correctly retrieve the call stack result, specify English as the message locale.

**GET\_HASH\_VALUE**

- A hash value based on the input string where the hash value should be between base and base + hash\_size - 1.

**Example**

```

PERFORM DBMS_UTILITY.GET_HASH_VALUE('abcdef', 0, 10000);

```

**CANONICALIZE**

- The procedure handles a single reserved or key word (such as 'table'), and strips off white spaces for a single identifier so that ' table ' becomes TABLE.

**Example**

```

declare
    l_result    text := '';
begin
    dbms_output.serveroutput(True);
    dbms_utility.canonicalize('table', l_result, 100);
    dbms_output.put_line(l_result);
end;
/

```

**COMMA\_TO\_TABLE**

- These procedures converts a comma-delimited list of names into a PL/SQL table of names.
- The list must be a non-empty comma-delimited list: Anything other than a comma-delimited list is rejected. Commas inside double quotes do not count.

**Example**

```
declare
    tablen          int4;
    tab             text[];
begin
    dbms_output.serveroutput(True);
    dbms_utility.comma_to_table('table, "Table", "Table,122324" ,
    Tablesd', tablen, tab);
    dbms_output.put_line(tablen);
    dbms_output.put_line(array_to_string(tab, ','));
end;
/
```

### TABLE\_TO\_COMMA

- This procedure converts a PL/SQL table of names into a comma-delimited list of names.

#### Example

```
declare
    tablen          int4;
    l_str           text;
begin
    dbms_output.serveroutput(True);

    dbms_utility.table_to_comma('{table, " \"table
\"\", \"\"table.1234567890\" \"\", \" tablezx\",NULL}'::text[], tablen,
    l_str);
    dbms_output.put_line(tablen);
    dbms_output.put_line(l_str);

end;
/
```

### DB\_VERSION

- This procedure returns version information for the database.

#### Example

```
declare
    lt_version      text;
    compatibility   text;
begin
    dbms_output.serveroutput(True);
    dbms_utility.db_version(lt_version, compatibility);
    dbms_output.put_line(lt_version);
    dbms_output.put_line(oracle.nvl(compatibility, 'NULL'));
end;
/
```

### EXEC\_DDL\_STATEMENT

- his procedure executes the DDL statement in parse\_string.

#### Example

```
declare
  l_result          text := '';
begin
  dbms_output.serveroutput(True);
  dbms_utility.exec_ddl_statement('create table if not exists
public.test_exec_ddl_stmt (id int, name text);');
end;
/
```

### GET\_TIME

- This function returns a measure of current time in hundredths of a second. The difference between the times returned from two calls measures the total elapsed time (not just CPU processing time) between those two points.

#### Example

```
DO $$
DECLARE
  start_time integer;
  end_time integer;
BEGIN
  start_time := DBMS_UTILITY.GET_TIME();
  PERFORM pg_sleep(2);
  end_time := DBMS_UTILITY.GET_TIME();
  -- clamp long runtime on slow build machines to the 2s the
  testsuite is expecting
  IF end_time BETWEEN start_time + 300 AND start_time + 1000
  THEN end_time := start_time + 250; END IF;
  RAISE NOTICE 'Execution time: % seconds',
trunc((end_time - start_time)::numeric/100);
END
$$;
```

### F.56.6.7.2. Usage Example

A usage example of DBMS\_UTILITY is shown below.

```
CREATE FUNCTION dbms_utility1_exe() RETURNS VOID AS $$
DECLARE
  s_StackTrace TEXT;
  v_hashvalue numeric(38,0);
BEGIN
  s_StackTrace := DBMS_UTILITY.FORMAT_CALL_STACK();
  RAISE NOTICE '%', s_StackTrace;
  v_hashvalue := DBMS_UTILITY.GET_HASH_VALUE('abcdef',0,10000);
  RAISE NOTICE 'v_hashvalue=%', v_hashvalue;
END;
$$ LANGUAGE plpgsql;

CREATE FUNCTION dbms_utility2_exe() RETURNS VOID AS $$
BEGIN
  PERFORM dbms_utility1_exe();
END;
```

```

$$ LANGUAGE plpgsql;

SELECT dbms_utility2_exe();
DROP FUNCTION dbms_utility2_exe();
DROP FUNCTION dbms_utility1_exe();

declare
    l_result          text := '';
begin
    dbms_output.serveroutput(True);
    dbms_utility.exec_ddl_statement('create table if not exists
public.test_exec_ddl_stmt (id int, name text);');
    l_result := dbms_metadata.get_ddl('table',
'test_exec_ddl_stmt');
    dbms_output.put_line(l_result);
    dbms_utility.exec_ddl_statement(' truncate table
public.test_exec_ddl_stmt');
    dbms_output.put_line('truncate SUCCESS');
    dbms_utility.exec_ddl_statement('drop table if exists
public.test_exec_ddl_stmt ; ');
    dbms_output.put_line('drop SUCCESS');
end;
/

```

## F.56.6.8. DBMS\_JOB

### Overview

Schedules and manages jobs in the It\_cron.

**Table F.129. DBMS\_JOB Features**

Feature	Description
BROKEN	Disables job execution.(invalid)
CHANGE	Alters any of the user-definable parameters associated with a job.
INSTANCE	Assigns a job to be run by a instance.(invalid)
INTERVAL	Alters the interval between executions for a specified job.
NEXT_DATE	Alters the next execution time for a specified job.(invalid)
REMOVE	Removes specified job from the job queue.
RUN	Forces a specified job to run.(invalid)
SUBMIT	Submits a new job to the job queue.
USER_EXPORT	Re-creates a given job for export.
WHAT	Alters the job description for a specified job.

### Syntax

```

CHANGE(job INT8,what TEXT,next_date TIMESTAMP,interval
TEXT,instance INT4 default null,force BOOL default 'false')
INTERVAL(job INT8,interval TEXT)
REMOVE(job INT8)

```

```
SUBMIT(job INT8,what TEXT,next_date TIMESTAMP default
sysdate,interval TEXT default 'null',no_parse BOOL default
'false',instance INT4 default null,force BOOL default 'false')
USER_EXPORT(job INT8,mycall TEXT)
WHAT(job INT8,what TEXT)
```

### F.56.6.8.1. Description of Features

This section explains each feature of `dbms_job`.

#### **CHANGE**

- This procedure changes any of the fields a user can set in a job.

#### **Example**

```
dbms_job.change(l_job_id, 'select 3', sysdate, '0 11 * * *');
```

#### **INTERVAL**

- This procedure changes how often a job runs.
- The interval parameter format is `lt_cron`'s format.

#### **Example**

```
dbms_job.interval(l_job_id, '0 11 * * *');
```

#### **REMOVE**

- This procedure removes an existing job from the job queue.

#### **Example**

```
dbms_job.remove(2);
```

#### **SUBMIT**

- This procedure submits a new job.
- The job submitted by this procedure will not have name. It's suggested to submit by `'select cron.Schedule(name,xxx)'`.

#### **Example**

```
dbms_job.submit(l_job_id, 'select 1',sysdate, '0 10 * * *');
```

#### **USER\_EXPORT**

- Produces the text of a call to re-create the given job.

#### **Example**

```
dbms_job.user_export(2, l_result);
```

#### WHAT

- This procedure changes what an existing job does.

#### Example

```
dbms_job.what(2, 'select 2');
```

### F.56.6.8.2. Usage Example

A usage example of DBMS\_JOB is shown below.

```
declare
    l_job_id    int8;
    l_result    text := '';
begin
    dbms_output.serveroutput(true);

    -- use dbms_job.submit will not have jobname
    dbms_job.submit(l_job_id, 'select 1',sysdate, '0 10 * * *');
    dbms_output.put_line('submit job, job id: '||l_job_id);

    dbms_job.user_export(l_job_id, l_result);
    dbms_output.put_line('user_export(job id: '||l_job_id||'): '||
l_result);

    -- update can't be used for job without name
    dbms_job.what(l_job_id, 'select 2');
    dbms_job.user_export(l_job_id, l_result);
    dbms_output.put_line('after dbms_job.what user_export(job
id: '||l_job_id||'): '||l_result);

    dbms_job.interval(l_job_id, '0 11 * * *');
    dbms_job.user_export(l_job_id, l_result);
    dbms_output.put_line('after dbms_job.interval user_export(job
id: '||l_job_id||'): '||l_result);

    dbms_job.change(l_job_id, 'select 3', sysdate, '0 11 * * *');
    dbms_job.user_export(l_job_id, l_result);
    dbms_output.put_line('after dbms_job.change user_export(job
id: '||l_job_id||'): '||l_result);

    dbms_job.next_date(l_job_id, sysdate);
    dbms_job.broken(l_job_id, True);
    dbms_job.instance(l_job_id, 10);
    dbms_job.run(l_job_id);

    dbms_job.remove(l_job_id);

end;
/
```

## F.56.6.9. DBMS\_LOCK

### Overview

Provides an interface to Lock Management services.

**Table F.130. DBMS\_LOCK Features**

Feature	Description
sleep	Puts a session to sleep for a specific time.

### Syntax

```
SLEEP(pi_seconds FLOAT8)
```

### F.56.6.9.1. Description of Features

This section explains each feature of dbms\_job.

#### SLEEP

- This procedure suspends the session for a specified period of time.
- suspends in seconds, to suspend the session.

#### Example

```
dbms_lock.sleep(0.1);
```

## F.56.6.10. DBMS\_METADATA

### Overview

Provides a way for you to retrieve metadata from the database dictionary.

**Table F.131. DBMS\_METADATA Features**

Feature	Description
get_ddl	Let you fetch metadata for objects.

### Syntax

```
GET_DDL(object_type VARCHAR,name VARCHAR,schema VARCHAR
DEFAULT current_schema(),VARCHAR DEFAULT 'COMPATIBLE',VARCHAR
DEFAULT 'ORACLE',VARCHAR DEFAULT 'DDL',BOOL DEFAULT 'false')
RETURNS TEXT
```

### F.56.6.10.1. Description of Features

This section explains each feature of dbms\_job.

**GET\_DDL**

- Let you fetch metadata for objects.

**Example**

```
select dbms_metadata.get_ddl('constraint', 'key1_check') from dual;
```

**F.56.6.11. DBMS\_OBFUSCATION\_TOOLKIT****Overview**

Enables an application to encrypt data using either the Data Encryption Standard (DES) or the Triple DES algorithms.

**Table F.132. DBMS\_OBFUSCATION\_TOOLKIT Features**

Feature	Description
md5	Generates MD5 hashes of data.

**Syntax**

```
MD5(input_string TEXT) RETURNS RAW
```

**F.56.6.11.1. Description of Features**

This section explains each feature of dbms\_job.

**MD5**

- Generates MD5 hashes of data.

**Example**

```
select dbms_obfuscation_toolkit.md5(input_string => '##')::text
from dual;
```

**F.56.6.12. DBMS\_SNAPSHOT****Overview**

Enables you to refresh snapshots(MVIEW).

**Table F.133. DBMS\_SNAPSHOT Features**

Feature	Description
refresh	Refreshes a list of snapshots.

**Syntax**

```
REFRESH(list TEXT,method TEXT default 'C')
```

### F.56.6.12.1. Description of Features

This section explains each feature of `dbms_job`.

#### REFRESH

- This procedure refreshes a list of snapshots(MVIEW).

#### Example

```
select
  dbms_snapshot.refresh('mv_test_dbms_snapshot,mv_test_dbms_snapshot1')
from dual;
```

### F.56.6.13. UTL\_FILE

#### Overview

Text files can be written and read using PL/pgSQL.

To perform these file operations, the directory for the operation target must be registered in the `UTL_FILE.UTL_FILE_DIR` table beforehand. Use the `INSERT` statement as the database administrator or a user who has `INSERT` privileges to register the directory. Also, if the directory is no longer necessary, delete it from the same table. Refer to "Registering and Deleting Directories" for information on the how to register and delete the directory.

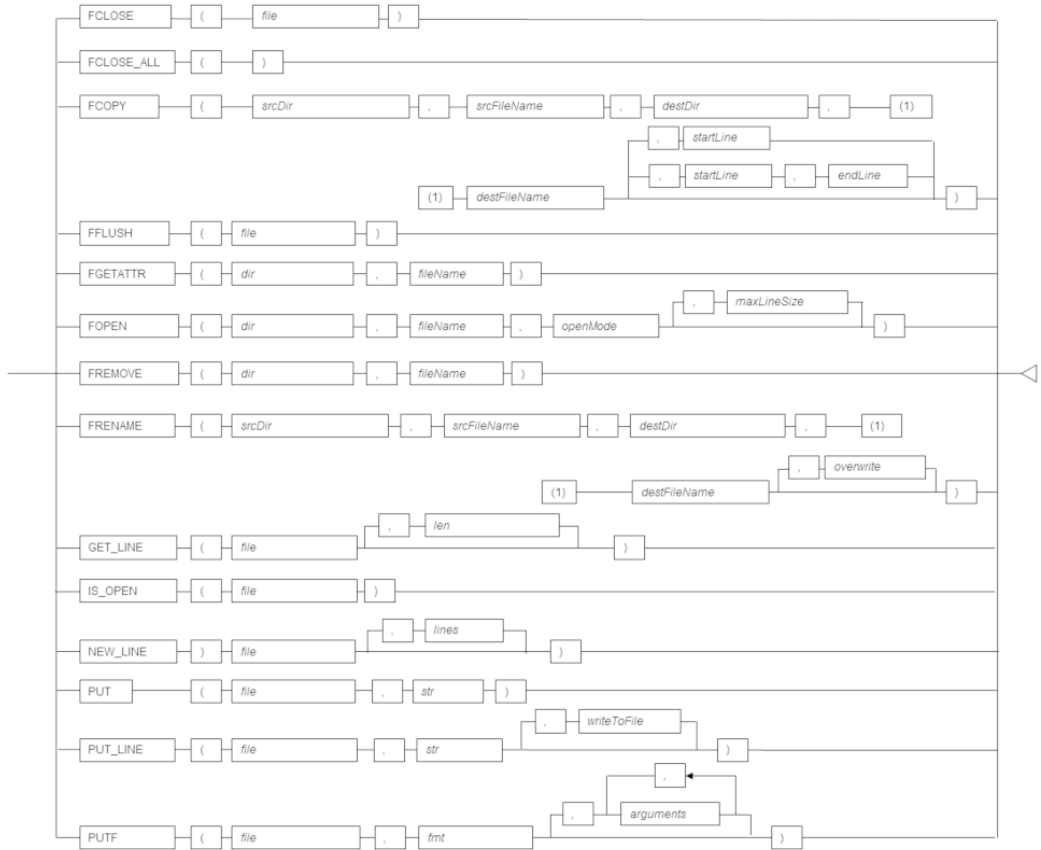

Declare the file handler explained hereafter as follows in PL/pgSQL:

```
DECLARE f UTL_FILE.FILE_TYPE;
```

**Table F.134. UTL\_FILE Features**

Feature	Description
FCLOSE	Closes a file.
FCLOSE_ALL	Closes all files open in a session.
FCOPY	Copies a whole file or a contiguous portion thereof.
FFLUSH	Flushes the buffer.
FGETATTR	Retrieves the attributes of a file.
FOPEN	Opens a file.
FREMOVE	Deletes a file.
FRENAME	Renames a file.
GET_LINE	Reads a line from a text file.
IS_OPEN	Checks if a file is open.
NEW_LINE	Writes newline characters.
PUT	Writes a string.
PUT_LINE	Appends a newline character to a string and writes the string.
PUTF	Writes a formatted string.

#### Syntax

### F.56.6.13.1. Registering and Deleting Directories

#### Registering the directory

1. Check if the directory is already registered (if it is, then step 2 is not necessary).

```
SELECT * FROM UTL_FILE.UTL_FILE_DIR WHERE dir='/home/pgsql';
```

2. Register the directory.

```
INSERT INTO UTL_FILE.UTL_FILE_DIR VALUES('/home/pgsql');
```

#### Deleting the directory

```
DELETE FROM UTL_FILE.UTL_FILE_DIR WHERE dir='/home/lightdb';
```

### F.56.6.13.2. Description

This section explains each feature of UTL\_FILE.

#### FCLOSE

- FCLOSE closes a file that is open.
- Specify an open file handle.

- The value returned is a NULL value.

**Example**

```
f := UTL_FILE.FCLOSE(f);
```

**FCLOSE\_ALL**

- FCLOSE\_ALL closes all files open in a session.
- Files closed with FCLOSE\_ALL can no longer be read or written.

**Example**

```
PERFORM UTL_FILE.FCLOSE_ALL();
```

**FCOPY**

- FCOPY copies a whole file or a contiguous portion thereof. The whole file is copied if *startLine* and *endLine* are not specified.
- Specify the directory location of the source file.
- Specify the source file.
- Specify the directory where the destination file will be created.
- Specify the name of the destination file.
- Specify the line number at which to begin copying. Specify a value greater than 0. If not specified, 1 is used.
- Specify the line number at which to stop copying. If not specified, the last line number of the file is used.

**Example**

```
PERFORM UTL_FILE.FCOPY('/home/lightdb', 'regress_ltsql.txt',  
'/home/lightdb', 'regress_ltsql2.txt');
```

**FFLUSH**

- FFLUSH forcibly writes the buffer data to a file.
- Specify an open file handle.

**Example**

```
PERFORM UTL_FILE.FFLUSH(f);
```

**FGETATTR**

- FGETATTR retrieves file attributes: file existence, file size, and information about the block size of the file.

- Specify the directory where the file exists.
- Specify the relevant file name.
- Use a SELECT statement to obtain the file attributes, which are stored in the fexists, file\_length, and blocksize columns.
- The fexists column stores a boolean (TRUE/FALSE) value. If the file exists, fexists is set to TRUE. If the file does not exist, fexists is set to FALSE. The data type of fexists is BOOLEAN.
- The file\_length column stores the length of the file in bytes. If the file does not exist, file\_length is NULL. The data type of file\_length is INTEGER.
- The blocksize column stores the block size of the file in bytes. If the file does not exist, blocksize is NULL. The data type of blocksize is INTEGER.

**Example**

```
SELECT fexists, file_length, blocksize INTO file_flag,
file_len, size
FROM UTL_FILE.FGETATTR('/home/lightdb', 'regress_ltsql.txt');
```

**FOPEN**

- FOPEN opens a file.
- Specify the directory where the file exists.
- Specify the file name.
- Specify the mode for opening the file:  
r: Read  
w: Write  
a: Add
- Specify the maximum string length (in bytes) that can be processed with one operation. If omitted, the default is 1024. Specify a value from 1 to 32767.
- Up to 50 files per session can be open at the same time.

**Example**

```
f := UTL_FILE.FOPEN('/home/
pgsql', 'regress_pgsql.txt', 'r', 1024);
```

**FREMOVE**

- FREMOVE deletes a file.
- Specify the directory where the file exists.
- Specify the file name.

**Example**

```
PERFORM UTL_FILE.REMOVE( '/home/lightdb',  
'regress_ltsql.txt' );
```

### **FRENAME**

- FRENAME renames a file.
- Specify the directory location of the source file.
- Specify the source file to be renamed.
- Specify the directory where the renamed file will be created.
- Specify the new name of the file.
- Specify whether to overwrite a file if one exists with the same name and in the same location as the renamed file. If TRUE is specified, the existing file will be overwritten. If FALSE is specified, an error occurs. If omitted, FALSE is set.

### **See**

Refer to "The SQL Language" > "Data Types" > "Boolean Type" in the LightDB Documentation for information on boolean type (TRUE/FALSE) values.

### **Example**

```
PERFORM UTL_FILE.FRENAME( '/home/lightdb', 'regress_ltsql.txt',  
'/home/lightdb', 'regress_ltsql2.txt', TRUE );
```

### **GET\_LINE**

- GET\_LINE reads a line from a file.
- Specify the file handle returned by FOPEN using r (read) mode.
- Specify the number of bytes to read from the file. If not specified, the maximum string length specified at FOPEN will be used.
- The return value is the buffer that receives the line read from the file.
- Newline characters are not loaded to the buffer.
- An empty string is returned if a blank line is loaded.
- Specify the maximum length (in bytes) of the data to be read. Specify a value from 1 to 32767. If not specified, the maximum string length specified at FOPEN is set. If no maximum string length is specified at FOPEN, 1024 is set.
- If the line length is greater than the specified number of bytes to read, the remainder of the line is read on the next call.
- A NO\_DATA\_FOUND exception will occur when trying to read past the last line.

### **Example**

```
buff := UTL_FILE.GET_LINE(f);
```

### **IS\_OPEN**

- IS\_OPEN checks if a file is open.
- Specify the file handle.
- The return value is a BOOLEAN type. TRUE represents an open state and FALSE represents a closed state.

**See**

Refer to "The SQL Language" > "Data Types" > "Boolean Type" in the LightDB Documentation for information on boolean type (TRUE/FALSE) values.

**Example**

```
IF UTL_FILE.IS_OPEN(f) THEN
    PERFORM UTL_FILE.FCLOSE(f);
END IF;
```

**NEW\_LINE**

- NEW\_LINE writes one or more newline characters.
- Specify an open file handle.
- Specify the number of newline characters to be written to the file. If omitted, "1" is used.

**Example**

```
PERFORM UTL_FILE.NEW_LINE(f, 2);
```

**PUT**

- PUT writes a string to a file.
- Specify the file handle that was opened with FOPEN using w (write) or a (append).
- Specify the string to be written to the file.
- The maximum length (in bytes) of the string to be written is the maximum string length specified at FOPEN.
- PUT does not append a newline character. To append a newline character, execute NEW\_LINE.

**Example**

```
PERFORM UTL_FILE.PUT(f, 'ABC');
```

**PUT\_LINE**

- PUT\_LINE appends a newline character to a string and writes the string.
- Specify the file handle that was opened with FOPEN w (write) or a (append).
- Specify whether to forcibly write to the file. If TRUE is specified, file writing is forced. If FALSE is specified, file writing is asynchronous. If omitted, FALSE will be set.
- The maximum length of the string (in bytes) is the maximum string length specified at FOPEN.

**Example**

```
PERFORM UTL_FILE.PUT_LINE(f, 'ABC', TRUE);
```

**PUTF**

- PUTF writes a formatted string.
- Specify the file handle that was opened with FOPEN w (write) or a (append).
- Specify the format, which is a string that includes the formatting characters \n and %s.
- The \n in the format is code for a newline character.
- Specify the same number of input values as there are %s in the format. Up to a maximum of five input values can be specified. The %s in the format are replaced with the corresponding input characters. If an input value corresponding to %s is not specified, it is replaced with an empty string.

**Example**

```
PERFORM UTL_FILE.PUTF(f, '[1=%s, 2=%s, 3=%s, 4=%s, 5=%s]\n',  
'1', '2', '3', '4', '5');
```

**F.56.6.13.3. Usage Example**

The procedure when using UTL\_FILE, and a usage example, are shown below.

**1. Preparation**

Before starting a new job that uses UTL\_FILE, register the directory in the UTL\_FILE.UTL\_FILE\_DIR table.

Refer to "Registering and Deleting Directories" for information on how to register the directory.

**2. Performing a job**

Perform a job that uses UTL\_FILE. The example is shown below.

```
CREATE OR REPLACE FUNCTION gen_file(mydir TEXT, infile TEXT,  
outfile TEXT, copyfile TEXT) RETURNS void AS $$  
  DECLARE  
    v1 VARCHAR(32767);  
    inf UTL_FILE.FILE_TYPE;  
    otf UTL_FILE.FILE_TYPE;  
  BEGIN  
    inf := UTL_FILE.FOPEN(mydir, infile, 'r', 256);  
    otf := UTL_FILE.FOPEN(mydir, outfile, 'w');  
    v1 := UTL_FILE.GET_LINE(inf, 256);  
    PERFORM UTL_FILE.PUT_LINE(otf, v1, TRUE);  
    v1 := UTL_FILE.GET_LINE(inf, 256);  
    PERFORM UTL_FILE.PUTF(otf, '%s\n', v1);  
    v1 := UTL_FILE.GET_LINE(inf, 256);  
    PERFORM UTL_FILE.PUT(otf, v1);  
    PERFORM UTL_FILE.NEW_LINE(otf);  
    PERFORM UTL_FILE.FFLUSH(otf);
```

```

inf := UTL_FILE.FCLOSE(inf);
otf := UTL_FILE.FCLOSE(otf);

PERFORM UTL_FILE.FCOPY(mydir, outfile, mydir, copyfile, 2,
3);
PERFORM UTL_FILE.FRENAME(mydir, outfile, mydir,
'rename.txt');

END;
$$ LANGUAGE plpgsql;

SELECT gen_file('/home/pgsql', 'input.txt', 'output.txt',
'copyfile.txt');

```

### 3. Post-processing

If you remove a job that uses UTL\_FILE, delete the directory information from the UTL\_FILE.UTL\_FILE\_DIR table. Ensure that the directory information is not being used by another job before deleting it.

Refer to "Registering and Deleting Directories" for information on how to delete the directory.

## F.56.6.14. UTL\_RAW

### Overview

Provides SQL functions for manipulating RAW datatypes.

**Table F.135. UTL\_RAW Features**

Feature	Description
BIT_AND	Performs bitwise logical "and" of the values in RAW r1 with RAW r2 and returns the "anded" result RAW.
BIT_COMPLEMENT	Performs bitwise logical "complement" of the values in RAW r and returns the "complement'ed" result RAW.
BIT_OR	Performs bitwise logical "or" of the values in RAW r1 with RAW r2 and returns the "or'd" result RAW.
BIT_XOR	Performs bitwise logical "exclusive or" of the values in RAW r1 with RAW r2 and returns the "xor'd" result RAW.
CAST_FROM_BINARY_INTEGER	Returns the RAW binary representation of a BINARY_INTEGER value.
CAST_FROM_NUMBER	Returns the RAW binary representation of a NUMBER value.
CAST_TO_BINARY_INTEGER	Casts the RAW binary representation of a BINARY_INTEGER into a BINARY_INTEGER.
CAST_TO_NUMBER	Casts the RAW binary representation of a NUMBER into a NUMBER.
CAST_TO_RAW	Converts a text value into a RAW value.
CAST_TO_VARCHAR2	Converts a RAW value into a text value.

Feature	Description
COMPARE	Compares RAW r1 against RAW r2.
CONCAT	Concatenates up to 12 RAWs into a single RAW.
CONVERT	Converts RAW r from character set from_charset to character set to_charset and returns the resulting RAW.
COPIES	Returns n copies of r concatenated together.
LENGTH	Returns the length in bytes of a RAW r.
OVERLAY	Overlays the specified portion of target RAW with overlay RAW, starting from byte position pos of target and proceeding for len bytes.
REVERSE	Reverses a byte sequence in RAW r from end to end.
TRANSLITERATE	Translates the bytes in the input RAW r according to the bytes in the translation RAWs from_set and to_set.
TRANSLATE	Converts the bytes in the input RAW r according to the bytes in the transliteration RAWs from_set and to_set.
XRANGE	Reverses a byte sequence in RAW r from end to end.
REVERSE	Returns a RAW containing all valid 1-byte encodings in succession, beginning with the value start_byte and ending with the value end_byte.

### Syntax

```

CAST_TO_VARCHAR2(r raw) RETURNS TEXT
CAST_TO_RAW(c TEXT) RETURNS RAW
CONCAT(r1 RAW,r2 RAW,r3 RAW,r4 RAW,r5 RAW,r6 RAW,r7 RAW,r8 RAW,r9
RAW,r10 RAW,r11 RAW,r12 RAW) RETURNS RAW
LENGTH(r RAW) RETURNS INT4
SUBSTR(r RAW,pos INT4,len INT4 DEFAULT null) RETURNS RAW
TRANSLITERATE(r RAW,to_set RAW DEFAULT ''::raw ,from_set RAW
DEFAULT ''::raw,pad RAW DEFAULT '00'::raw) RETURNS RAW
TRANSLATE(r RAW,from_set RAW,to_set RAW) RETURNS RAW
COPIES(r RAW,n INT8) RETURNS RAW
OVERLAY(overlay_str RAW,target RAW,pos INT4 DEFAULT 1,len INT4
DEFAULT NULL,pad RAW DEFAULT '00'::raw) RETURNS RAW
XRANGE(start_byte RAW,end_byte RAW) RETURNS RAW
REVERSE(r RAW) RETURNS RAW
COMPARE(r1 RAW,r2 RAW,pad RAW) RETURNS INT4
CONVERT(r RAW,to_charset TEXT,from_charset TEXT) RETURNS RAW
BIT_AND(r1 RAW,r2 RAW) RETURNS RAW
BIT_OR(r1 RAW,r2 RAW) RETURNS RAW
BIT_XOR(r1 RAW,r2 RAW) RETURNS RAW
BIT_COMPLEMENT(r RAW) RETURNS RAW
CAST_TO_NUMBER(r RAW)RETURNS NUMERIC
CAST_FROM_NUMBER(n NUMERIC) RETURNS RAW
CAST_TO_BINARY_INTEGER(r RAW,endianess INT)RETURNS INT4
CAST_FROM_BINARY_INTEGER(n INT4,endianess INT) RETURNS RAW

```

### F.56.6.14.1. Description of Features

This section explains each feature of `dbms_job`.

#### **CAST\_TO\_VARCHAR2**

- This function converts a RAW value represented using some number of data bytes into a text value with that number of data bytes.

#### **Example**

```
select utl_raw.cast_to_varchar2('43616D65726F6E') from dual;
```

#### **CAST\_TO\_RAW**

- This function converts a text value represented using some number of data bytes into a RAW value with that number of data bytes. The data itself is not modified in any way, but its datatype is recast to a RAW datatype.

#### **Example**

```
select utl_raw.cast_to_raw('##') from dual;
```

#### **CONCAT**

- This function concatenates up to 12 RAWs into a single RAW.

#### **Example**

```
select utl_raw.concat('1', '0102', 'f', '1a2b' ) from dual;
```

#### **LENGTH**

- This function returns the length in bytes of a RAW `r`.

#### **Example**

```
select UTL_RAW.length('FFFF'::raw) from dual;
```

#### **SUBSTR**

- If `pos` is positive, then `SUBSTR` counts from the beginning of `r` to find the first byte. If `pos` is negative, then `SUBSTR` counts backward from the end of the `r`. The value `pos` can be 0.

#### **Example**

```
select utl_raw.substr('0102030405', 3, 2 ) from dual;
```

#### **TRANSLITERATE**

- This function converts the bytes in the input RAW `r` according to the bytes in the transliteration RAWs `from_set` and `to_set`. Successive bytes in `r` are looked up in the `from_set`, and, if not found,

copied unaltered to the result RAW. If found, then they are replaced in the result RAW by either corresponding bytes in the to\_set, or the pad byte when no correspondence exists.

**Example**

```
select utl_raw.transliterate( '010203040502', '0709', '01020304',  
  'ff' ) from dual;
```

**TRANSLATE**

- This function translates the bytes in the input RAW r according to the bytes in the translation RAWs from\_set and to\_set. If a byte in r has a matching byte in from\_set, then it is replaced by the byte in the corresponding position in to\_set, or deleted.

**Example**

```
select utl_raw.translate( '0102030405', '0304', '09' ) from dual;
```

**COPIES**

- This function returns n copies of r concatenated together.

**Example**

```
select utl_raw.copies( '010203', 3 ) from dual;
```

**OVERLAY**

- This function overlays the specified portion of target RAW with overlay\_str RAW, starting from byte position pos of target and proceeding for len bytes.
- If overlay\_str has less than len bytes, then it is extended to len bytes using the pad byte. If overlay\_str exceeds len bytes, then the extra bytes in overlay\_str are ignored. If len bytes beginning at position pos of target exceeds the length of target, then target is extended to contain the entire length of overlay\_str.

**Example**

```
select utl_raw.overlay( 'aabb', '010203', 5, 1, 'FF' ) from dual;
```

**XRANGE**

- This function returns a RAW value containing the succession of one-byte encodings beginning and ending with the specified byte-codes.
- If the start\_byte value is greater than the end\_byte value, then the succession of resulting bytes begins with start\_byte, wraps through x'FF' back to x'00', then ends at end\_byte.

**Example**

```
select utl_raw.xrange( 'FA', '01' ) from dual;
```

**REVERSE**

- This function reverses a byte sequence in RAW r from end to end. For example, x'0102F3' would be reversed to x'F30201', and 'xyz' would be reversed to 'zyx'. The result length is the same as the input RAW length.

**Example**

```
select utl_raw.reverse( '010203040506070809' ) from dual;
```

**COMPARE**

- This function compares two RAW values. If they differ in length, then the shorter is extended on the right according to the optional pad parameter.

**Example**

```
select utl_raw.compare( '010203', '01020304', '04' ) from dual;
```

**CONVERT**

- This function converts RAW r from character set from\_charset to character set to\_charset and returns the resulting RAW.
- Both from\_charset and to\_charset must be supported character sets defined to the LightDB server.

**Example**

```
select utl_raw.convert( rawout( '##'::BYTEA)::text::raw, 'GBK', 'UTF8' )  
from dual;
```

**BIT\_AND**

- This function performs bitwise logical "and" of the values in RAW r1 with RAW r2 and returns the "anded" result RAW.
- If r1 and r2 differ in length, the shorter of the two RAWs will extend to same length by add '00'. (it is not same with oracle).

**Example**

```
select utl_raw.bit_and('1234ffdd', 'fff1234f') from dual;
```

**BIT\_OR**

- This function performs bitwise logical "or" of the values in RAW r1 with RAW r2 and returns the or'd result RAW.
- If r1 and r2 differ in length, the shorter of the two RAWs will extend to same length by add '00'. (it is not same with oracle).

**Example**

```
select utl_raw.bit_or('1234ffdd', 'fff1234f') from dual;
```

### **BIT\_XOR**

- This function performs bitwise logical "exclusive or" of the values in RAW r1 with RAW r2 and returns the xor'd result RAW.
- If r1 and r2 differ in length, the shorter of the two RAWs will extend to same length by add '00'. (it is not same with oracle).

#### **Example**

```
select utl_raw.bit_xor('1234ffdd','1234ffee') from dual;
```

### **BIT\_COMPLEMENT**

- This function performs bitwise logical "complement" of the values in RAW r and returns the complement'ed result RAW. The result length equals the input RAW r length.

#### **Example**

```
select UTL_raw.bit_complement('1122FF') from dual;
```

### **CAST\_TO\_NUMBER**

- This function casts the RAW binary representation of a NUMBER into a NUMBER.

#### **Example**

```
select utl_raw.cast_TO_number('C10215') from dual;
```

### **CAST\_FROM\_NUMBER**

- This function returns the RAW binary representation of a NUMBER value.

#### **Example**

```
select UTL_raw.cast_from_number(1.2) from dual;
```

### **CAST\_TO\_BINARY\_INTEGER**

- This function casts the RAW binary representation of a INTEGER into a INTEGER.(oracle is BINARY\_INTEGER)

#### **Example**

```
select utl_raw.cast_to_binary_integer('FF00') from dual;
```

### **CAST\_FROM\_BINARY\_INTEGER**

- This function returns the RAW binary representation of a INTEGER value.(oracle is BINARY\_INTEGER)

#### **Example**

```
select utl_raw.cast_from_binary_integer(65280) from dual;
```

## F.56.6.15. UTL\_URL

### Overview

Has two functions that provide escape and unescape mechanisms for URL characters.

**Table F.136. UTL\_URL Features**

Feature	Description
ESCAPE	Returns a URL with illegal characters (and optionally reserved characters) escaped using the %2-digit-hex-code format.
UNESCAPE	Unescapes the escape character sequences to their original forms in a URL. Convert the %XX escape character sequences to the original characters.

### Syntax

```
ESCAPE(url TEXT,escape_reserved_chars BOOL DEFAULT
FALSE,url_charset TEXT DEFAULT 'UTF8') RETURNS TEXT
UNESCAPE(url TEXT,url_charset TEXT DEFAULT 'UTF8') RETURNS TEXT
```

### F.56.6.15.1. Description of Features

This section explains each feature of dbms\_job.

#### ESCAPE

- This function returns a URL with illegal characters (and optionally reserved characters) escaped using the %2-digit-hex-code format.

#### Example

```
select utl_url.escape('http://###.com') from dual;
```

#### UNESCAPE

- This function unescapes the escape character sequences to its original form in a URL, to convert the %XX escape character sequences to the original characters.

#### Example

```
select utl_url.unescape('http%3A%2F%2F
%E6%96%B0%E5%B9%B4%E5%A5%BD.com', 'utf8') from dual;
```

## F.56.6.16. UTL\_ENCODE

### Overview

Provides functions that encode RAW data into a standard encoded format.

**Table F.137. UTL\_ENCODE Features**

Feature	Description
BASE64_DECODE	Reads the base 64-encoded RAW input string and decodes it to its original RAW value.
BASE64_ENCODE	Encodes the binary representation of the RAW value into base 64 elements and returns it in the form of a RAW string.
MIMEHEADER_DECODE	Decodes a string from mime header format.
MIMEHEADER_ENCODE	Encodes a string into mime header format.
QUOTED_PRINTABLE_DECODE	Reads the text quoted printable format input string and decodes it to the corresponding RAW string.
QUOTED_PRINTABLE_ENCODE	Reads the RAW input string and encodes it to the corresponding quoted printable format string.
TEXT_DECODE	Decodes a character set sensitive text string.
TEXT_ENCODE	Encodes a character set sensitive text string.
UUDECODE	Reads the RAW uuencode format input string and decodes it to the corresponding RAW string.
UUENCODE	Reads the RAW input string and encodes it to the corresponding uuencode format string.

**Syntax**

```

BASE64_DECODE(r RAW) RETURNS RAW
BASE64_ENCODE(r RAW) RETURNS RAW
MIMEHEADER_DECODE(buf TEXT) RETURNS TEXT
MIMEHEADER_ENCODE(buf TEXT,encode_charset TEXT default
  'UTF8'::text,encoding INT4 default 2::int4) RETURNS TEXT
QUOTED_PRINTABLE_DECODE(r RAW) RETURNS RAW
QUOTED_PRINTABLE_ENCODE(r RAW) RETURNS RAW
TEXT_DECODE(buf TEXT,encode_charset TEXT default
  'UTF8'::text,encoding INT4 default 2::int4) RETURNS TEXT
TEXT_ENCODE(buf TEXT,encode_charset TEXT default
  'UTF8'::text,encoding INT4 default 2::int4) RETURNS TEXT
UUDECODE(r RAW) RETURNS RAW
UUENCODE(r RAW,type INT default 1::int,filename TEXT default
  'uuencode.txt',permission TEXT default '0') RETURNS RAW

```

**F.56.6.16.1. Description of Features**

This section explains each feature of dbms\_job.

**BASE64\_DECODE**

- This function reads the base 64-encoded RAW input string and decodes it to its original RAW value.

**Example**

```
select utl_encode.base64_decode('3572574C364B2B56') from dual;
```

**BASE64\_ENCODE**

- This function encodes the binary representation of the RAW value into base 64 elements and returns it in the form of a RAW string.

**Example**

```
select utl_encode.base64_encode(rawtohex('##')::raw) from dual;
```

**MIMEHEADER\_DECODE**

- Decodes a string from mime header format(=?<charset> ?<encoding> ?<encoded text>?= ').

**Example**

```
select UTL_ENCODE.mimeheader_decode('=?UTF-8?Q?
What=20is=20the=20date=20=E7=8E=8B=20=3D20=20/=20\=3F?= ' ) from
dual;
```

**MIMEHEADER\_ENCODE**

- This function produces as output an "encoded word" of the form(=?<charset> ?<encoding> ?<encoded text>?= ').
- The ENCODING input parameter accepts as valid values UTL\_ENCODE.QUOTED\_PRINTABLE or UTL\_ENCODE.BASE64 or NULL. If NULL, quoted-printable encoding is selected as a default value.
- The <charset> value is specified as the input parameter encode\_charset.

**Example**

```
select utl_encode.MIMEHEADER_ENCODE('What is the date # =20 / \?',
encode_charset =>'UTF8', encoding => 1 ) from dual;
```

**QUOTED\_PRINTABLE\_DECODE**

- This function reads the raw quoted printable format input string and decodes it to the corresponding RAW string.

**Example**

```
select
utl_encode.quoted_printable_decode('3D45353D42453D3830313233345C61732064663D33
from dual;
```

**QUOTED\_PRINTABLE\_ENCODE**

- This function reads the RAW input string and encodes it to the corresponding quoted printable format string.

**Example**

```
select
utl_encode.quoted_printable_decode('3D45353D42453D3830313233345C61732064663D33
from dual;
```

**TEXT\_DECODE**

- This function converts the input text to the target character set as specified by the `encode_charset` parameter, if not NULL. The encoded text is converted to the base character set of database.
- You can decode from either quoted-printable or base64 format, with regard to each encoding parameter. 1 for base64, 2 for quoted-printable, default is quoted-printable format.

**Example**

```
select utl_encode.text_decode('=CD=F91234\as
df=3DAB',encode_charset => 'GBK',encoding => 2) from dual;
```

**TEXT\_ENCODE**

- This function converts the input text to the target character set as specified by the `encode_charset` parameter, if not NULL. The text is encoded to either base64 or quoted-printable format, as specified by the encoding parameter.

**Example**

```
select utl_encode.text_encode('#12\as df=AB',encode_charset =>
'GBK', encoding => 1) from dual;
```

**UUDECODE**

- This function reads the RAW uuencode format input string and decodes it to the corresponding RAW string.

**Example**

```
select UTL_ENCODE.uudecode(rawtohex(' ,6[C9&5FA$R,S0`')::raw) from
dual;
```

**UUENCODE**

- This function reads the RAW input string and encodes it to the corresponding uuencode format string.

**Example**

```
select UTL_ENCODE.uuencode('5BB8D91959A113233340')::raw) from dual;
```

## F.56.7. Transaction behavior

Most of the transaction behavior are exactly same, however the below stuff is not.

### F.56.7.1. Handled Statement Failure.

```
create table t (a int primary key, b int);
begin;
insert into t values(1,1);
insert into t values(1, 1);
commit;
```

Oracle : commit can succeed. t has 1 row after that.

LightDB: commit failed due to the 2nd insert failed. so t has 0 row.

## F.56.7.2. DML with Subquery

Case 1:

```
create table dml(a int, b int);
insert into dml values(1, 1), (2,2);

-- session 1:
begin;
delete from dml where a in (select min(a) from dml);

--session 2:
delete from dml where a in (select min(a) from dml);

-- session 1:
commit;
```

In Oracle: 1 row deleted in sess 2. so 0 rows in the dml at last.

In LightDB: 0 rows are deleted in sess 2, so 1 rows in the dml at last.

Oracle probably detects the min(a) is changed and rollback/rerun the statement.

The same reason can cause the below difference as well.

```
create table su (a int, b int);
insert into su values(1, 1);

- session 1:
begin;
update su set b = 2 where b = 1;

- sess 2:
select * from su where a in (select a from su where b = 1) for
update;

- sess 1:
commit;
```

In Oracle, 0 row is selected. In LightDB, 1 row (1, 2) is selected.

A best practice would be never use subquery in DML & SLEECT ... FOR UPDATE. Even in Oracle, the behavior is inconsistent as well. Oracle between 11.2.0.1 and 11.2.0.3 probably behavior same as LightDB, but other versions not.

## F.56.8. System View Reference

These views are based on oracle 11g, but some views include some fields from the new version.

Views are created under oracle and sys schema.

In order to be compatible with oracle, the following views have the same fields as the corresponding views in oracle , but return NULL for those fields whose field values cannot be obtained or are difficult to obtain.

The supported fields are listed below. Some fields have different meanings from oracle.

### F.56.8.1. [DBA/ALL/USER]\_SEQUENCES

- DBA\_SEQUENCES describes all sequences in the database.
- The ALL\_SEQUENCES view is currently the same as the DBA\_SEQUENCES view, and no permission verification is done like oracle.
- USER\_SEQUENCES describes all sequences owned by the current user.

**Table F.138. ALL\_SEQUENCES**

Column	Description
SEQUENCE_OWNER	Owner of the sequence
SEQUENCE_NAME	Sequence name
MIN_VALUE	Minimum value of the sequence
MAX_VALUE	Maximum value of the sequence
INCREMENT_BY	Value by which sequence is incremented
CYCLE_FLAG	Indicates whether the sequence wraps around on reaching the limit (Y) or not (N)
ORDER_FLAG	Indicates whether sequence numbers are generated in order (Y) or not (N), Under lightdb this is always Y
CACHE_SIZE	Number of sequence numbers to cache
LAST_NUMBER	Last sequence number written to disk.

### F.56.8.2. [DBA/ALL/USER]\_SYNONYMS

- SYNONYMS is not supported in LightDB yet, so these view are empty now.

### F.56.8.3. [DBA/ALL/USER]\_TAB\_COLS, COLS, [DBA/ALL/USER]\_TAB\_COLUMNS

- DBA\_TAB\_COLS describes the columns of all tables, views in the database.
- The ALL\_TAB\_COLS view is currently the same as the DBA\_TAB\_COLS view, and no permission verification is done like oracle.
- USER\_TAB\_COLS describes the columns of the tables and views owned by the current user. This view does not display the OWNER column.
- COLS is same with USER\_TAB\_COLS.
- DBA\_TAB\_COLUMNS describes the columns of all tables and views in the database.

- The ALL\_TAB\_COLUMNS view is currently the same as the DBA\_TAB\_COLUMNS view, and no permission verification is done like oracle.
- USER\_TAB\_COLUMNS describes the columns of the tables and views owned by the current user. This view does not display the OWNER column.
- [DBA/ALL/USER]\_TAB\_COLS view differs from [DBA/ALL/USER]\_TAB\_COLUMNS in that hidden columns are not filtered out(HIDDEN\_COLUMN,VIRTUAL\_COLUMN,SEGMENT\_COLUMN\_ID,INTERNAL\_COLUMN\_ID).

**Table F.139. ALL\_TAB\_COLS**

Column	Description
OWNER	Owner of the table, view
TABLE_NAME	Name of the table, view
COLUMN_NAME	Column name
DATA_TYPE	Datatype of the column
DATA_TYPE_OWNER	Owner of the datatype of the column
DATA_LENGTH	Length of the column (in char for character Types; in byte for other types, for number/ numeric it is always 22)
DATA_PRECISION	Decimal precision for NUMBER datatype; binary precision for FLOAT datatype; NULL for all other datatypes
DATA_SCALE	Digits to the right of the decimal point in a number
NULLABLE	Indicates whether a column allows NULLs. The value is N if there is a NOT NULL constraint on the column or if the column is part of a PRIMARY KEY
COLUMN_ID	Sequence number of the column as created
DEFAULT_LENGTH	Length of the default value for the column
DATA_DEFAULT	Default value for the column
NUM_DISTINCT	Number of distinct values in the column
NUM_NULLS	Number of NULLs in the column
AVG_COL_LEN	Average length of the column (in bytes)
CHAR_LENGTH	Displays the length of the column in characters
CHAR_USED	Indicates that the column uses BYTE length semantics (B) or CHAR length semantics (C), or whether the datatype is not any of the following (NULL)

#### F.56.8.4. [DBA/ALL/USER]\_TAB\_COL\_STATISTICS

- DBA\_TAB\_COL\_STATISTICS contains column statistics and histogram information extracted from "DBA\_TAB\_COLUMNS". Its columns are the same as those in "ALL\_TAB\_COL\_STATISTICS".
- The ALL\_TAB\_COL\_STATISTICS view is currently the same as the DBA\_SEQUENCES view, and no permission verification is done like oracle.
- USER\_TAB\_COL\_STATISTICS displays such information extracted from "USER\_TAB\_COLUMNS". This view does not display the OWNER column.

**Table F.140. ALL\_TAB\_COL\_STATISTICS**

Column	Description
OWNER	Owner of the table
TABLE_NAME	Name of the table
COLUMN_NAME	Column name
NUM_DISTINCT	Number of distinct values in the column
NUM_NULLS	Number of NULLs in the column
AVG_COL_LEN	Average length of the column (in bytes)

**F.56.8.5. [DBA/ALL/USER]\_OBJECTS, OBJ**

- DBA\_OBJECTS describes all objects in the database. Its columns are the same as those in "ALL\_OBJECTS".
- The ALL\_OBJECTS view is currently the same as the DBA\_OBJECTS view, and no permission verification is done like oracle.
- USER\_OBJECTS describes all objects owned by the current user. This view does not display the OWNER column.
- OBJ is same with USER\_OBJECTS.

**Table F.141. ALL\_OBJECTS**

Column	Description
OWNER	Owner of the object
OBJECT_NAME	Name of the object
SUBOBJECT_NAME	Name of the subobject (for example, partition), NULL if not exist
OBJECT_ID	Dictionary object number of the object
DATA_OBJECT_ID	Dictionary object number of the segment that contains the object
OBJECT_TYPE	Type of the object
STATUS	Status of the object: VALID, INVALID
TEMPORARY	Indicates whether the object is temporary (the current session can see only data that it placed in this object itself) (Y) or not (N)

**F.56.8.6. [DBA/ALL/USER]\_CATALOG**

- DBA\_CATALOG lists all tables, views, and sequences in the database(no cluster and synonyms).
- The ALL\_CATALOG view is currently the same as the DBA\_CATALOG view, and no permission verification is done like oracle.
- USER\_OCATALOG displays the tables, views, and sequences in the current user's schema.
- All column in oracle view is supported.

**Table F.142. ALL\_CATALOG**

Column	Description
OWNER	Owner of the TABLE, VIEW, SEQUENCE

Column	Description
TABLE_NAME	Name of the TABLE, VIEW, SEQUENCE
TABLE_TYPE	Type of the TABLE, VIEW, SEQUENCE

### F.56.8.7. DICTIONARY, DICT

- DICTIONARY/DICT contains descriptions of data dictionary tables and views.

**Table F.143. DICTIONARY**

Column	Description
TABLE_NAME	Name of the object
COMMENTS	Text comment on the object

### F.56.8.8. [DBA/ALL/USER]\_DEPENDENCIES

- DBA\_DEPENDENCIES describes all dependencies in the database between procedures, packages, functions, package bodies, and triggers, including dependencies on views created without any database links. This view does not display the SCHEMAID column.
- The ALL\_DEPENDENCIES view is currently the same as the DBA\_DEPENDENCIES view, and no permission verification is done like oracle.
- USER\_DEPENDENCIES describes dependencies between objects in the current user's schema. This view does not display the OWNER column.

**Table F.144. ALL\_DEPENDENCIES**

Column	Description
OWNER	Owner of the object
NAME	Name of the object
TYPE	Type of the object
REFERENCED_OWNER	Owner of the referenced object (remote owner if remote object)
REFERENCED_NAME	Name of the referenced object
REFERENCED_TYPE	Type of the referenced object
DEPENDENCY_TYPE	Type of the dependency (oracle: Indicates whether the dependency is a REF dependency (REF) or not (HARD))

### F.56.8.9. [DBA/ALL/USER]\_SOURCE

- DBA\_SOURCE describes the text source of all stored objects in the database.
- The ALL\_SOURCE view is currently the same as the DBA\_SOURCE view, and no permission verification is done like oracle.
- USER\_SOURCE describes the text source of the stored objects owned by the current user. This view does not display the OWNER column.

**Table F.145. ALL\_SOURCE**

Column	Description
OWNER	Owner of the object

Column	Description
NAME	Name of the object
TYPE	Type of object: FUNCTION, PACKAGE, PACKAGE BODY, PROCEDURE, TRIGGER
LINE	Line number of this line of source
TEXT	Text source of the stored object

### F.56.8.10. [DBA/ALL/USER]\_PROCEDURES

- DBA\_PROCEDURES lists all functions and procedures, along with associated properties.
- The ALL\_PROCEDURES view is currently the same as the DBA\_PROCEDURES view, and no permission verification is done like oracle.
- USER\_PROCEDURES lists all functions and procedures owned by the current user, along with associated properties. It does not contain the OWNER column.
- These views indicates whether or not a function is pipelined, parallel enabled or an aggregate function. If a function is pipelined or an aggregate function, the associated implementation type (if any) is also identified.

**Table F.146. ALL\_PROCEDURES**

Column	Description
OWNER	Owner of the procedure
OBJECT_NAME	Name of the object: top-level function, procedure, or package name
OBJECT_ID	Object number of the object
OBJECT_TYPE	The typename of the object
AGGREGATE	Indicates whether the procedure is an aggregate function (YES) or not (NO)
PARALLEL	Indicates whether the procedure or function is parallel-enabled (YES) or not (NO)
DETERMINISTIC	YES, if the procedure/function is declared to be deterministic; otherwise NO

### F.56.8.11. [DBA/ALL/USER]\_TRIGGERS

- DBA\_TRIGGERS describes all triggers in the database.
- The ALL\_TRIGGERS view is currently the same as the DBA\_TRIGGERS view, and no permission verification is done like oracle.
- USER\_TRIGGERS describes the triggers owned by the current user

**Table F.147. ALL\_TRIGGERS**

Column	Description
OWNER	Owner of the trigger
TRIGGER_NAME	Name of the trigger
TRIGGER_TYPE	When the trigger fires: BEFORE STATEMENT, BEFORE EACH ROW, AFTER STATEMENT, AFTER EACH ROW, INSTEAD OF EACH ROW

Column	Description
TRIGGERING_EVENT	DML that fires the trigger
TABLE_OWNER	Owner of the table on which the trigger is defined
BASE_OBJECT_TYPE	Base object on which the trigger is defined: TABLE, VIEW
TABLE_NAME	Indicates the table or view name on which the trigger is defined
REFERENCING_NAMES	Names used for referencing OLD and NEW column values from within the trigger
WHEN_CLAUSE	Must evaluate to TRUE for TRIGGER_BODY to execute
STATUS	Indicates whether the trigger is enabled (ENABLED) or disabled (DISABLED); a disabled trigger will not fire
ACTION_TYPE	Action type of the trigger body: 'PL/SQL'
TRIGGER_BODY	Statements executed by the trigger when it fires
BEFORE_STATEMENT	Indicates whether the trigger has a BEFORE STATEMENT section (YES) or not (NO)
BEFORE_ROW	Indicates whether the trigger has a BEFORE EACH ROW section (YES) or not (NO)
AFTER_ROW	Indicates whether the trigger has an AFTER EACH ROW section (YES) or not (NO)
AFTER_STATEMENT	Indicates whether the trigger has an AFTER STATEMENT section (YES) or not (NO)
INSTEAD_OF_ROW	Indicates whether the trigger has an INSTEAD OF section (YES) or not (NO)

### F.56.8.12. [DBA/ALL/USER]\_TRIGGER\_COLS

- DBA\_TRIGGER\_COLS describes the use of columns in all triggers in the database.
- The ALL\_TRIGGER\_COLS view is currently the same as the DBA\_TRIGGER\_COLS view, and no permission verification is done like oracle.
- USER\_TRIGGER\_COLS describes the use of columns in the triggers owned by the current user and in triggers on tables owned by the current user.

**Table F.148. ALL\_TRIGGER\_COLS**

Column	Description
TRIGGER_OWNER	Owner of the trigger
TRIGGER_NAME	Name of the trigger
TABLE_OWNER	Owner of the table on which the trigger is defined
TABLE_NAME	Table on which the trigger is defined
COLUMN_NAME	Name of the column used in the trigger

### F.56.8.13. [DBA/ALL/USER]\_TYPES

- DBA\_TYPES describes all object types in the database.

- The ALL\_TYPES view is currently the same as the DBA\_TYPES view, and no permission verification is done like oracle.
- USER\_TYPES describes the object types owned by the current user. This view does not display the OWNER column.

**Table F.149. ALL\_TYPES**

Column	Description
OWNER	Owner of the type
TYPE_NAME	Name of the type
TYPE_OID	Object identifier (OID) of the type
TYPECODE	Typecode of the type
PREDEFINED	Indicates whether the type is a predefined type (YES) or not (NO)

### F.56.8.14. [DBA/ALL/USER]\_CONSTRAINTS

- DBA\_CONSTRAINTS describes all constraint definitions in the database.
- The ALL\_CONSTRAINTS view is currently the same as the DBA\_CONSTRAINTS view, and no permission verification is done like oracle.
- USER\_CONSTRAINTS describes constraint definitions on tables in the current user's schema.

**Table F.150. ALL\_CONSTRAINTS**

Column	Description
OWNER	Owner of the constraint definition
CONSTRAINT_NAME	Name of the constraint definition
CONSTRAINT_TYPE	Type of the constraint definition  c - Check constraint on a table  p - Primary key  u - Unique key  f - Constraint that involves a REF column  t - Constraint triggers  t - exclusivity Constraint
TABLE_NAME	Name associated with the table (or view) with the constraint definition
SEARCH_CONDITION	Text of search condition for a check constraint
R_OWNER	Owner of the table referred to in a referential constraint
DELETE_RULE	Delete rule for a referential constraint: 'NO ACTION', 'RESTRICT', 'CASCADE', 'SET NULL', 'SET DEFAULT'
STATUS	Enforcement status of the constraint: 'ENABLED', 'DISABLED'
DEFERRABLE	Indicates whether the constraint is deferrable (DEFERRABLE) or not (NOT DEFERRABLE)

Column	Description
DEFERRED	Indicates whether the constraint was initially deferred (DEFERRED) or not (IMMEDIATE)
VALIDATED	Has the constraint been validated? Currently, can be false only for foreign keys and CHECK constraints
INDEX_OWNER	Name of the user owning the index
INDEX_NAME	Name of the index (only shown for unique, primary key, foreign key, or exclusion constraint)
INVALID	Indicates whether the constraint is invalid (INVALID) or not (NULL)

### F.56.8.15. [DBA/ALL/USER]\_CONS\_COLUMNS

- DBA\_CONS\_COLUMNS describes all columns in the database that are specified in constraints.
- The ALL\_CONS\_COLUMNS view is currently the same as the DBA\_CONS\_COLUMNS view, and no permission verification is done like oracle.
- USER\_CONS\_COLUMNS describes columns that are owned by the current user and that are specified in constraints.
- All column in oracle are supported

**Table F.151. ALL\_CONS\_COLUMNS**

Column	Description
OWNER	Owner of the constraint definition
CONSTRAINT_NAME	Name of the constraint definition
TABLE_NAME	Name of the table with the constraint definition
COLUMN_NAME	Name of the column or attribute of the object type column specified in the constraint definition
POSITION	Original position of the column or attribute in the definition of the object

### F.56.8.16. [DBA/ALL/USER]\_VIEWS

- DBA\_VIEWS describes all views in the database.
- The ALL\_VIEWS view is currently the same as the DBA\_VIEWS view, and no permission verification is done like oracle.
- USER\_VIEWS describes the views owned by the current user. This view does not display the OWNER column.

**Table F.152. ALL\_VIEWS**

Column	Description
OWNER	Owner of the view
VIEW_NAME	Name of the view
TEXT_LENGTH	Length of the view text

Column	Description
TEXT	View text

### F.56.8.17. [DBA/ALL/USER]\_TABLES, [DBA/ALL/USER]\_ALL\_TABLES, TAB

- DBA\_ALL\_TABLES describes all object tables and relational tables in the database.
- The ALL\_ALL\_TABLES view is currently the same as the DBA\_ALL\_TABLES view, and no permission verification is done like oracle.
- USER\_ALL\_TABLES describes the object tables and relational tables owned by the current user. This view does not display the OWNER column.
- [DBA/ALL/USER]\_TABLES does not display the OBJECT\_ID\_TYPE, TABLE\_TYPE\_OWNER and TABLE\_TYPE column.
- [DBA/ALL/USER]\_TABLES has RESULT\_CACHE column, but [DBA/ALL/USER]\_ALL\_TABLES does not.
- TABS is same with USER\_TABLES.

**Table F.153. ALL\_ALL\_TABLES**

Column	Description
OWNER	Owner of the table
TABLE_NAME	Name of the table
TABLESPACE_NAME	Name of the tablespace containing the table
LOGGING	Indicates whether or not changes to the table are logged
NUM_ROWS	Number of rows in the table
BLOCKS	Number of used blocks in the table
AVG_ROW_LEN	Average row length, including row overhead
LAST_ANALYZED	Date on which the table was most recently analyzed
PARTITIONED	Indicates whether the table is partitioned (YES) or not (NO)
TEMPORARY	Indicates whether the table is temporary (Y) or not (N)
ROW_MOVEMENT	If a partitioned table, indicates whether row movement is enabled (ENABLED) or disabled (DISABLED)  Always is 'ENABLE'

### F.56.8.18. [DBA/ALL/USER]\_TAB\_STATISTICS

- DBA\_TAB\_STATISTICS displays optimizer statistics for all tables in the database.
- The ALL\_TAB\_STATISTICS view is currently the same as the DBA\_TAB\_STATISTICS view, and no permission verification is done like oracle.
- USER\_TAB\_STATISTICS displays optimizer statistics for the tables owned by the current user. This view does not display the OWNER column.

- [DBA/ALL/USER]\_TABLES does not display the OBJECT\_ID\_TYPE, TABLE\_TYPE\_OWNER and TABLE\_TYPE column.

**Table F.154. ALL\_TAB\_STATISTICS**

Column	Description
OWNER	Owner of the object
TABLE_NAME	Name of the table
TABLESPACE_NAME	Name of the tablespace containing the table
PARTITION_NAME	Name of the partition
PARTITION_POSITION	Position of the partition within the table
OBJECT_TYPE	Type of the object#TABLE, PARTIOTION, SUBPARTITION
NUM_ROWS	Number of rows in the object
BLOCKS	Number of used blocks in the object
AVG_ROW_LEN	Average row length, including row overhead
LAST_ANALYZED	Date of the most recent time the table was analyzed

### F.56.8.19. [DBA/ALL/USER]\_TAB\_COMMENTS

- DBA\_TAB\_COMMENTS displays comments on all tables and views in the database.
- The ALL\_TAB\_COMMENTS view is currently the same as the DBA\_TAB\_COMMENTS view, and no permission verification is done like oracle.
- USER\_TAB\_COMMENTS displays comments on the tables and views owned by the current user. This view does not display the OWNER column.

**Table F.155. ALL\_TAB\_COMMENTS**

Column	Description
OWNER	Owner of the object
TABLE_NAME	Name of the object
TABLE_TYPE	Type of the object
COMMENTS	Comment on the object

### F.56.8.20. [DBA/ALL/USER]\_COL\_COMMENTS

- DBA\_COL\_COMMENTS displays comments on the columns of all tables and views in the database.
- The ALL\_COL\_COMMENTS view is currently the same as the DBA\_COL\_COMMENTS view, and no permission verification is done like oracle.
- USER\_COL\_COMMENTS displays comments on the columns of the tables and views owned by the current user. This view does not display the OWNER column.

**Table F.156. ALL\_COL\_COMMENTS**

Column	Description
OWNER	Owner of the object

Column	Description
TABLE_NAME	Name of the object
COLUMN_NAME	Name of the column
COMMENTS	Name of the column

### F.56.8.21. [DBA/ALL/USER]\_TAB\_MODIFICATIONS

- DBA\_TAB\_MODIFICATIONS describes such information for all tables in the database.
- The ALL\_TAB\_MODIFICATIONS view is currently the same as the DBA\_TAB\_MODIFICATIONS view, and no permission verification is done like oracle.
- USER\_TAB\_MODIFICATIONS describes such information for tables owned by the current user. This view does not display the TABLE\_OWNER column.

**Table F.157. ALL\_TAB\_MODIFICATIONS**

Column	Description
TABLE_OWNER	Owner of the modified table
TABLE_NAME	Name of the modified table
INSERTS	Approximate number of inserts since the last time statistics were gathered
UPDATES	Approximate number of updates since the last time statistics were gathered
DELETES	Approximate number of deletes since the last time statistics were gathered
TIMESTAMP	Indicates the last time the table was modified

### F.56.8.22. [DBA/ALL/USER]\_INDEXES, IND

- DBA\_INDEXES describes all indexes in the database.
- The ALL\_INDEXES view is currently the same as the DBA\_INDEXES view, and no permission verification is done like oracle.
- USER\_INDEXES describes the indexes owned by the current user. This view does not display the OWNER column.
- IND is same with USER\_INDEXES.

**Table F.158. ALL\_INDEXES**

Column	Description
OWNER	Owner of the index
INDEX_NAME	Name of the index
INDEX_TYPE	Type of the index, always NORMAL
TABLE_OWNER	Owner of the indexed object
TABLE_NAME	Name of the indexed object
TABLE_TYPE	Type of the indexed object: TABLE, VIEW, INDEX, SEQUENCE
UNIQUENESS	Indicates whether the index is unique (UNIQUE) or nonunique (NONUNIQUE)

Column	Description
TABLESPACE_NAME	Name of the tablespace containing the index
LOGGING	Indicates whether or not changes to the index are logged: 'YES', 'NO'
DISTINCT_KEYS	Number of distinct indexed values
STATUS	Indicates whether a nonpartitioned index is VALID or UNUSABLE
NUM_ROWS	Number of rows in the index
LAST_ANALYZED	Date on which this index was most recently analyzed
PARTITIONED	Indicates whether the index is partitioned (YES) or not (NO)
TEMPORARY	Indicates whether the index is on a temporary table (Y) or not (N)

### F.56.8.23. [DBA/ALL/USER]\_INDEX\_USAGE

- DBA\_INDEX\_USAGE displays cumulative statistics for each index.
- The ALL\_INDEX\_USAGE view is same with DBA\_INDEX\_USAGE(this view is not exist in oracle).
- USER\_INDEX\_USAGE describes cumulative statistics for each index owned by the current user(this view is not exist in oracle). This view does not display the OWNER column.

**Table F.159. DBA\_INDEX\_USAGE**

Column	Description
OBJECT_ID	Object ID for the index
NAME	Index name
OWNER	Index owner
TOTAL_ACCESS_COUNT	Total number of times the index has been accessed
TOTAL_ROWS_RETURNED	Total rows returned by the index

### F.56.8.24. [DBA/ALL/USER]\_IND\_COLUMNS

- DBA\_IND\_COLUMNS describes the columns of indexes on all tables in the database.
- The ALL\_IND\_COLUMNS view is currently the same as the DBA\_IND\_COLUMNS view, and no permission verification is done like oracle.
- USER\_IND\_COLUMNS describes the columns of indexes owned by the current user and columns of indexes on tables owned by the current user. This view does not display the INDEX\_OWNER or TABLE\_OWNER columns.

**Table F.160. ALL\_IND\_COLUMNS**

Column	Description
INDEX_OWNER	Owner of the index
INDEX_NAME	Name of the index
TABLE_OWNER	Owner of the table

Column	Description
TABLE_NAME	Name of the table
COLUMN_NAME	Column name or attribute of the object type column
COLUMN_POSITION	Position of the column or attribute within the index
COLUMN_LENGTH	Indexed length of the column, for number/numeric it is always 22
CHAR_LENGTH	Maximum codepoint length of the column
DESCEND	Indicates whether the column is sorted in descending order (DESC) or ascending order (ASC)

### F.56.8.25. [DBA/ALL/USER]\_IND\_EXPRESSIONS

- DBA\_IND\_EXPRESSIONS describes the expressions of all function-based indexes in the database.
- The ALL\_IND\_EXPRESSIONS view is currently the same as the DBA\_IND\_COLUMNS view, and no permission verification is done like oracle.
- USER\_IND\_EXPRESSIONS describes the expressions of function-based indexes on tables owned by the current user. This view does not display the INDEX\_OWNER or TABLE\_OWNER columns.

**Table F.161. ALL\_IND\_EXPRESSIONS**

Column	Description
INDEX_OWNER	Owner of the index
INDEX_NAME	Name of the index
TABLE_OWNER	Owner of the table
TABLE_NAME	Name of the table
COLUMN_EXPRESSION	Function-based index expression defining the column
COLUMN_POSITION	Position of the column or attribute within the index

### F.56.8.26. [DBA/ALL/USER]\_IND\_STATISTICS

- DBA\_IND\_STATISTICS displays optimizer statistics for all indexes in the database.
- The ALL\_IND\_STATISTICS view is currently the same as the DBA\_IND\_STATISTICS view, and no permission verification is done like oracle.
- USER\_IND\_STATISTICS displays optimizer statistics for the indexes on the tables owned by the current user. This view does not display the OWNER column.

**Table F.162. ALL\_IND\_STATISTICS**

Column	Description
OWNER	Owner of the index
INDEX_NAME	Name of the index
TABLE_OWNER	Owner of the indexed object
TABLE_NAME	Name of the indexed object

Column	Description
PARTITION_NAME	Function-based index expression defining the column
PARTITION_POSITION	Position of the column or attribute within the index
OBJECT_TYPE	Type of the object:INDEX, PARTITION  Always 'INDEX' now, because this view will not to get partition info
DISTINCT_KEYS	Number of distinct keys in the index
NUM_ROWS	Number of rows in the index
LAST_ANALYZED	Date of the most recent time the index was analyzed

### F.56.8.27. [DBA/ALL/USER]\_USERS

- DBA\_USERS describes all users of the database, and contains more columns than ALL\_USERS.
- ALL\_USERS lists all users of the database (USERNAME, USER\_ID, CREATED), but no permission verification is done like oracle.
- USER\_USERS describes the current user, and contains more columns than ALL\_USERS.

**Table F.163. DBA\_USERS**

Column	Description
USERNAME	Name of the user
USER_ID	ID number of the user
PASSWORD	This column is deprecated in favor of the AUTHENTICATION_TYPE column
ACCOUNT_STATUS	Account status, always 'NORMAL'
EXPIRY_DATE	Date of expiration of the account

**Table F.164. ALL\_USERS**

Column	Description
USERNAME	Name of the user
USER_ID	ID number of the user

### F.56.8.28. DBA\_ROLES

- Describes all roles in the database

**Table F.165. DBA\_ROLES**

Column	Description
ROLE	Name of the role
PASSWORD_REQUIRED	This column is deprecated in favor of the AUTHENTICATION_TYPE column, always 'NO'
AUTHENTICATION_TYPE	Indicates the authentication mechanism for the role, always 'NONE'

Column	Description
	NONE - CREATE ROLE role1;
COMMON	Indicates whether a given role is common. always 'YES', does not exist in oracle 11g

### F.56.8.29. [DBA/USER]\_ROLE\_PRIVS

- DBA\_ROLE\_PRIVS describes the roles granted to all users and roles in the database.
- USER\_ROLE\_PRIVS describes the roles granted to the current user.

**Table F.166. DBA\_ROLE\_PRIVS**

Column	Description
GRANTEE	Name of the user or role receiving the grant
GRANTED_ROLE	Granted role name
ADMIN_OPTION	Indicates whether the grant was with the ADMIN OPTION (YES) or not (NO)
DEFAULT_ROLE	Indicates whether the role is designated as a DEFAULT ROLE for the user (YES) or not (NO)  Always 'NO'
COMMON	Indicates how the grant was made  always 'YES', does not exist in oracle 11g

### F.56.8.30. PRODUCT\_COMPONENT\_VERSION

- Contains version and status information for component products.

**Table F.167. PRODUCT\_COMPONENT\_VERSION**

Column	Description
PRODUCT	Product name
VERSION	Version number
STATUS	Status of release

### F.56.8.31. PLAN\_TABLE

- PLAN\_TABLE is automatically created as a global temporary table to hold the output of an EXPLAIN PLAN statement for all users.
- it is not supported by LightDB, so this view is empty for compatibility.

### F.56.8.32. DBA\_DATA\_FILES

- Describes database files

**Table F.168. DBA\_DATA\_FILES**

Column	Description
FILE_NAME	Name of the database file

Column	Description
FILE_ID	File identifier number of the database file
TABLESPACE_NAME	Name of the tablespace to which the file belongs
BYTES	Size of the file in bytes
BLOCKS	Size of the file in Oracle blocks
STATUS	File status: AVAILABLE or INVALID  Always 'AVAILABLE'
RELATIVE_FNO	Relative file number
AUTOEXTENSIBLE	Autoextensible indicator  Always 'YES'
INCREMENT_BY	Number of Oracle blocks used as autoextension increment
ONLINE_STATUS	Online status of the file  Always 'ONLINE'

### F.56.8.33. [DBA/ALL/USER]\_JOBS

- Get info from lt\_cron
- DBA\_JOBS describes all jobs in the database.
- USER\_JOBS describes the jobs owned by the current user.
- ALL\_JOBS is same with USER\_JOBS.

**Table F.169. DBA\_JOBS**

Column	Description
JOB	Identifier of job
LOG_USER	Login user when the job was submitted
PRIV_USER	User whose default privileges apply to this job
SCHEMA_USER	Default schema used to parse the job  Always 'CRON'
LAST_DATE	Date on which this job last successfully executed
LAST_SEC	Same as LAST_DATE. This is when the last successful execution started  'HH24:MI:SS' format
THIS_DATE	Date that this job started executing (usually null if not executing)
THIS_SEC	Same as THIS_DATE. This is when the last successful execution started  'HH24:MI:SS' format
TOTAL_TIME	Total wall clock time spent by the system on this job in the last executed  It is not same with oracle. In oracle, it means total wall clock time spent by the system on

Column	Description
	this job (in seconds) since the first time this job executed, and this value is cumulative
BROKEN	Y: no attempt is made to run this job, N: an attempt is made to run this job  Always 'N'
INTERVAL	String uses the standard cron syntax, ref to lt_cron  Different from oracle
WHAT	LightDB commands  Different from oracle

### F.56.8.34. DBA\_JOBS\_RUNNING

- Get info from lt\_cron
- Lists all jobs that are currently running in the instance.

**Table F.170. DBA\_JOBS\_RUNNING**

Column	Description
SID	Identifier of process that is executing the job
JOB	Identifier of job. This job is currently executing
LAST_DATE	Date on which this job last successfully executed
LAST_SEC	Same as LAST_DATE. This is when the last successful execution started  'HH24:MI:SS' format
THIS_DATE	Date that this job started executing (usually null if not executing)
THIS_SEC	Same as THIS_DATE. This is when the last successful execution started  'HH24:MI:SS' format

### F.56.8.35. [DBA/ALL/USER]\_MVIEWES

- DBA\_MVIEWS describes all materialized views in the database.
- The ALL\_MVIEWS view is currently the same as the DBA\_MVIEWS view, and no permission verification is done like oracle.
- USER\_MVIEWS describes all materialized views owned by the current user.

**Table F.171. ALL\_MVIEWS**

Column	Description
OWNER	Schema in which the materialized view was created
MVIEW_NAME	Name of the materialized view

Column	Description
CONTAINER_NAME	Name of the container in which the materialized view's data is held. Normally this is the same as MVIEW_NAME
QUERY	Query that defines the materialized view
QUERY_LEN	Length (in bytes) of the defining query
UPDATABLE	Indicates whether the materialized view is updatable (Y) or not (N)  Always 'N'
REFRESH_MODE	Refresh mode of the materialized view  Always 'DEMAND', it means database refreshes this materialized view whenever an appropriate refresh procedure is called
REFRESH_METHOD	Default method used to refresh the materialized view  Always 'COMPLETE'
BUILD_MODE	Indicates how the materialized view was populated during creation  Always 'IMMEDIATE'

### F.56.8.36. [DBA/ALL/USER]\_MVIEW\_LOGS

- It is not supported, so use as an empty view for compatibility.
- DBA\_MVIEW\_LOGS describes all materialized view logs in the database.
- ALL\_MVIEW\_LOGS describes all materialized view logs accessible to the current user.
- USER\_MVIEW\_LOGS describes all materialized view logs owned by the current user.

### F.56.8.37. [DBA/ALL/USER]\_MVIEW\_COMMENTS

- DBA\_MVIEW\_COMMENTS displays comments on the materialized views in the database.
- The ALL\_MVIEW\_COMMENTS view is currently the same as the DBA\_MVIEW\_COMMENTS view, and no permission verification is done like oracle.
- USER\_MVIEW\_COMMENTS displays comments on the materialized views owned by the current user. This view does not display the OWNER column.

**Table F.172. ALL\_MVIEW\_COMMENTS**

Column	Description
OWNER	Owner of the materialized view
MVIEW_NAME	Name of the materialized view
COMMENTS	Comment on the materialized view

### F.56.8.38. [DBA/USER]\_TABLESPACES

- DBA\_TABLESPACES describes all tablespaces in the database.

- USER\_TABLESPACES describes the tablespaces accessible to the current user. This view does not display the PLUGGED\_IN column.

**Table F.173. DBA\_TABLESPACES**

Column	Description
TABLESPACE_NAME	Name of the tablespace
BLOCK_SIZE	Tablespace block size (in bytes)
STATUS	Tablespace status Always 'ONLINE'
CONTENTS	Tablespace contents Always 'PERMANENT'

**F.56.8.39. NLS\_[DATABASE/INSTANCE/SESSION]\_PARAMETERS**

- NLS\_DATABASE\_PARAMETERS lists permanent NLS parameters of the database.
- NLS\_INSTANCE\_PARAMETERS lists NLS parameters of the instance.
- NLS\_SESSION\_PARAMETERS lists NLS parameters of the user session.

**Table F.174. NLS\_DATABASE\_PARAMETERS**

Column	Description
PARAMETER	Parameter name
VALUE	Parameter value

**F.56.8.40. [DBA/USER]\_SEGMENTS**

- DBA\_SEGMENTS describes the storage allocated for all segments in the database.
- USER\_SEGMENTS describes the storage allocated for the segments owned by the current user's objects. This view does not display the OWNER, HEADER\_FILE, HEADER\_BLOCK, or RELATIVE\_FNO columns.

**Table F.175. DBA\_SEGMENTS**

Column	Description
OWNER	Username of the segment owner
SEGMENT_NAME	Name, if any, of the segment
PARTITION_NAME	Object Partition Name (Set to NULL for non-partitioned objects)
SEGMENT_TYPE	Type of segment: 'TABLE', 'TABLE PARTITION', 'TABLE SUBPARTITION', 'INDEX', 'INDEX PARTITION', 'INDEX SUBPARTITION'
TABLESPACE_NAME	Name of the tablespace containing the segment
HEADER_FILE	Name of the tablespace containing the segment
BYTES	Size, in bytes, of the segments
BLOCKS	Size, in LightDB blocks, of the segment

### F.56.8.41. [DBA/USER/ALL]\_PART\_TABLES

- DBA\_PART\_TABLES displays the object-level partitioning information for all partitioned tables in the database.
- The ALL\_PART\_TABLES view is currently the same as the DBA\_PART\_TABLES view, and no permission verification is done like oracle.
- USER\_PART\_TABLES displays the object-level partitioning information for the partitioned tables owned by the current user. This view does not display the OWNER column.

The supported fields are listed below. unsupported fields are filed with NULL.

**Table F.176. ALL\_PART\_TABLES**

Column	Description
OWNER	Owner of the partitioned table
TABLE_NAME	Name of the partitioned table
PARTITIONING_TYPE	Type of the partitioning method: RANGE, HASH, LIST
SUBPARTITIONING_TYPE	Type of the composite partitioning method: RANGE, HASH, LIST
PARTITION_COUNT	Number of partitions in the table
PARTITIONING_KEY_COUNT	Number of columns in the partitioning key
SUBPARTITIONING_KEY_COUNT	For a composite-partitioned table, the number of columns in the subpartitioning key
DEF_TABLESPACE_NAME	Default tablespace to be used when adding a partition
DEF_LOGGING	Default LOGGING attribute to be used when adding a partition

### F.56.8.42. [DBA/USER/ALL]\_TAB\_PARTITIONS

- DBA\_TAB\_PARTITIONS displays partition-level partitioning information, partition storage parameters, and partition statistics for all partitions in the database.
- The ALL\_TAB\_PARTITIONS view is currently the same as the DBA\_TAB\_PARTITIONS view, and no permission verification is done like oracle.
- USER\_TAB\_PARTITIONS displays such information for the partitions of all partitioned objects owned by the current user. This view does not display the TABLE\_OWNER column.
- When a new partition is created, the partition name is identical to the name specified in ADD/CREATE/MODIFY statement, for range interval partition we prefix the partition name with "ap", for hash partition that did not has a explicit name, we prefix the partition name with "p".

**Table F.177. ALL\_TAB\_PARTITIONS**

Column	Description
TABLE_OWNER	Owner of the table
TABLE_NAME	Name of the table
COMPOSITE	Indicates whether the table is composite-partitioned (YES) or not (NO)
PARTITION_NAME	Name of the partition

Column	Description
SUBPARTITION_COUNT	If this is a composite partitioned table, the number of subpartitions in the partition
PARTITION_POSITION	Position of the partition within the table
TABLESPACE_NAME	Name of the tablespace containing the partition
LOGGING	Indicates whether or not changes to the table are logged
NUM_ROWS	Number of rows in the partition
BLOCKS	Number of used data blocks in the partition
LAST_ANALYZED	Date on which this partition was most recently analyzed

### F.56.8.43. [DBA/USER/ALL]\_TAB\_SUBPARTITIONS

- DBA\_TAB\_SUBPARTITIONS displays the subpartition name, name of the table and partition to which it belongs, its storage attributes, and statistics for all subpartitions in the database.
- The ALL\_TAB\_SUBPARTITIONS view is currently the same as the DBA\_TAB\_SUBPARTITIONS view, and no permission verification is done like oracle.
- USER\_TAB\_SUBPARTITIONS displays such information for subpartitions of all partitioned objects owned by the current user. This view does not display the TABLE\_OWNER column.
- When a new subpartition is created, the subpartition name is identical to the name specified in the ADD statement, and prefixed with its partition name while created in CREATE statement. When dealing with hash partitions that do not have an explicit name, we prepend the partition name with "p".

**Table F.178. ALL\_TAB\_SUBPARTITIONS**

Column	Description
TABLE_OWNER	Owner of the table
TABLE_NAME	Name of the table
PARTITION_NAME	Name of the partition
SUBPARTITION_NAME	Name of the subpartition
PARTITION_POSITION	Position of the partition within the table
SUBPARTITION_POSITION	Position of the subpartition within the partition
TABLESPACE_NAME	Name of the tablespace containing the partition
LOGGING	Indicates whether or not changes to the table are logged
NUM_ROWS	Number of rows in the subpartition
BLOCKS	Number of blocks in the subpartition
LAST_ANALYZED	Date on which this table was most recently analyzed

### F.56.8.44. [DBA/USER/ALL]\_PART\_KEY\_COLUMNS

- DBA\_PART\_KEY\_COLUMNS describes the partitioning key columns for all partitioned objects in the database.
- The ALL\_PART\_KEY\_COLUMNS view is currently the same as the DBA\_PART\_KEY\_COLUMNS view, and no permission verification is done like oracle.

- `USER_PART_KEY_COLUMNS` describes the partitioning key columns for the partitioned objects owned by the current user. This view does not display the `OWNER` column.

**Table F.179. ALL\_PART\_KEY\_COLUMNS**

Column	Description
<code>OWNER</code>	Owner of the partitioned table or index
<code>NAME</code>	Name of the partitioned table or index
<code>OBJECT_TYPE</code>	Object type: TABLE, INDEX
<code>COLUMN_NAME</code>	Name of the column
<code>COLUMN_POSITION</code>	Position of the column within the partitioning key

**F.56.8.45. [DBA/USER/ALL]\_SUBPART\_KEY\_COLUMNS**

- `DBA_SUBPART_KEY_COLUMNS` displays subpartitioning key columns for composite-partitioned tables (and local indexes on composite-partitioned tables) for all subpartitions in the database.
- The `ALL_SUBPART_KEY_COLUMNS` view is currently the same as the `DBA_SUBPART_KEY_COLUMNS` view, and no permission verification is done like oracle.
- `USER_SUBPART_KEY_COLUMNS` displays this information for subpartitions of all partitioned objects owned by the current user. This view does not display the `OWNER` column.

**Table F.180. ALL\_SUBPART\_KEY\_COLUMNS**

Column	Description
<code>OWNER</code>	Owner of the partitioned table or index
<code>NAME</code>	Name of the partitioned table or index
<code>OBJECT_TYPE</code>	Object type: TABLE, INDEX
<code>COLUMN_NAME</code>	Name of the column
<code>COLUMN_POSITION</code>	Position of the column within the subpartitioning key

**F.56.8.46. [DBA/USER/ALL]\_IND\_PARTITIONS**

- `DBA_IND_PARTITIONS` describes all index partitions in the database.
- The `ALL_IND_PARTITIONS` view is currently the same as the `DBA_IND_PARTITIONS` view, and no permission verification is done like oracle.
- `USER_IND_PARTITIONS` describes the index partitions owned by the current user. This view does not display the `INDEX_OWNER` column.

**Table F.181. ALL\_IND\_PARTITIONS**

Column	Description
<code>INDEX_OWNER</code>	Owner of the index
<code>INDEX_NAME</code>	Name of the index
<code>COMPOSITE</code>	Indicates whether the partition belongs to a local index on a composite-partitioned table (YES) or not (NO)
<code>PARTITION_NAME</code>	Name of the partition

Column	Description
SUBPARTITION_COUNT	If a local index on a composite-partitioned table, the number of subpartitions in the partition
PARTITION_POSITION	Position of the partition within the index
TABLESPACE_NAME	Name of the tablespace containing the partition
LOGGING	Indicates whether or not changes to the index are logged
NUM_ROWS	Number of rows returned
LAST_ANALYZED	Date on which this partition was most recently analyzed

### F.56.8.47. [DBA/USER/ALL]\_PART\_INDEXES

- DBA\_PART\_INDEXES displays the object-level partitioning information for all partitioned indexes in the database.
- The ALL\_PART\_INDEXES view is currently the same as the DBA\_PART\_INDEXES view, and no permission verification is done like oracle.
- USER\_PART\_INDEXES displays the object-level partitioning information for the partitioned indexes owned by the current user. This view does not display the OWNER column.

**Table F.182. ALL\_PART\_INDEXES**

Column	Description
OWNER	Owner of the partitioned index
INDEX_NAME	Name of the partitioned index
TABLE_NAME	Name of the partitioned table
PARTITIONING_TYPE	Type of the partitioning method: RANGE, HASH, LIST
SUBPARTITIONING_TYPE	Type of the composite partitioning method: RANGE, HASH, LIST
PARTITION_COUNT	Number of partitions in the index
PARTITIONING_KEY_COUNT	Number of columns in the partitioning key
SUBPARTITIONING_KEY_COUNT	For a composite-partitioned table, the number of columns in the subpartitioning key
LOCALITY	Indicates whether the partitioned index is local (LOCAL) or global (GLOBAL), always 'LOCAL'
ALIGNMENT	Indicates whether the partitioned index is prefixed (PREFIXED) or non-prefixed (NON_PREFIXED)
DEF_TABLESPACE_NAME	For a local index, the default tablespace to be used when adding or splitting a table partition
DEF_LOGGING	For a local index, the default LOGGING attribute to be used when adding a table partition

### F.56.8.48. COL

- COL describes the columns of the tables and views owned by the current user. This view does not display the OWNER column.

**Table F.183. COL**

Column	Description
TNAME	Name of the table, view
COLNO	Sequence number of the column as created
CNAME	Column name
COLTYPE	Datatype of the column
WIDTH	Length of the column(in char for character Types; in byte for other types, for number/ numeric it is always 22)
SCALE	Digits to the right of the decimal point in a number
PRECISION	Decimal precision for NUMBER datatype; binary precision for FLOAT datatype; NULL for all other datatypes
NULLS	Indicates whether a column allows NULLs. The value is 'NOT NULL' if there is a NOT NULL constraint on the column or if the column is part of a PRIMARY KEY
DEFAULTVAL	Default value for the column

## F.57. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

### F.57.1. General Functions

`get_raw_page(relname text, fork text, blkno int)` returns `bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. `fork` should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

`get_raw_page(relname text, blkno int)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all LightDB heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsn   | checksum | flags | lower | upper | special |
-----+-----+-----+-----+-----+-----+
0/24A1B50 |         0 |      1 |    232 |    368 |    8192 |
8192 |         4 |      0
```

The returned columns correspond to the fields in the `PageHeaderData` struct. See `src/include/storage/bufpage.h` for details.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno int4)` returns `smallint`

`page_checksum` computes the checksum for the page, as if it was located at the given block.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
       page_checksum
-----
          13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea)` returns `text`

`fsm_page_contents` shows the internal node structure of a FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm',
      0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

See `src/backend/storage/freespace/README` for more information on the structure of an FSM page.

## F.57.2. Heap Functions

`heap_page_items(page bytea)` returns `setof record`

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class',
      0));
```

See `src/include/storage/itemid.h` and `src/include/access/htup_details.h` for explanations of the fields returned.

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool])` returns `bytea[]`

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass,
    t_data, t_infomask, t_infomask2, t_bits) FROM
    heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

`heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool])` returns `setof record`

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM
    heap_page_item_attrs(get_raw_page('pg_class', 0),
    'pg_class'::regclass);
```

`heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer)` returns `record`

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
    FROM heap_page_items(get_raw_page('pg_class', 0)),
    LATERAL heap_tuple_infomask_flags(t_infomask,
    t_infomask2)
    WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT
    NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

See `src/include/access/htup_details.h` for explanations of the flag names returned.

## F.57.3. B-Tree Functions

`bt_metap(relname text)` returns `record`

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
magic          | 340322
version        | 4
root           | 1
level          | 0
fastroot       | 1
fastlevel      | 0
oldest_xact    | 582
last_cleanup_num_tuples | 1000
allequalimage  | f
```

bt\_page\_stats(relname text, blkno int) returns record

bt\_page\_stats returns summary information about single pages of B-tree indexes. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]-+-----
blkno          | 1
type           | 1
live_items     | 224
dead_items     | 0
avg_item_size  | 16
page_size      | 8192
free_size      | 3668
btpo_prev      | 0
btpo_next      | 0
btpo           | 0
btpo_flags     | 3
```

bt\_page\_items(relname text, blkno int) returns setof record

bt\_page\_items returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data,
dead, htid, tids[0:2] AS some_tids
FROM bt_page_items('tenk2_hundred', 5);
 itemoffset | ctid | itemlen | nulls | vars | data
            | dead | htid | some_tids
-----+-----+-----+-----+-----+-----
1 | (16,1) | 16 | f | f | 30 00 00 00
00 00 00 00
2 | (16,8292) | 616 | f | f | 24 00 00 00
00 00 00 00 | f | (1,6) | {"(1,6)", "(10,22)"}
3 | (16,8292) | 616 | f | f | 25 00 00 00
00 00 00 00 | f | (1,18) | {"(1,18)", "(4,22)"}
4 | (16,8292) | 616 | f | f | 26 00 00 00
00 00 00 00 | f | (4,18) | {"(4,18)", "(6,17)"}
5 | (16,8292) | 616 | f | f | 27 00 00 00
00 00 00 00 | f | (1,2) | {"(1,2)", "(1,19)"}
6 | (16,8292) | 616 | f | f | 28 00 00 00
00 00 00 00 | f | (2,24) | {"(2,24)", "(4,11)"}
7 | (16,8292) | 616 | f | f | 29 00 00 00
00 00 00 00 | f | (2,17) | {"(2,17)", "(11,2)"}

```

```

      8 | (16,8292) |      616 | f      | f      | 2a 00 00 00
00 00 00 00 | f      | (0,25) | {"(0,25)", "(3,20)"}
      9 | (16,8292) |      616 | f      | f      | 2b 00 00 00
00 00 00 00 | f      | (0,10) | {"(0,10)", "(0,14)"}
     10 | (16,8292) |      616 | f      | f      | 2c 00 00 00
00 00 00 00 | f      | (1,3)  | {"(1,3)", "(3,9)"}
     11 | (16,8292) |      616 | f      | f      | 2d 00 00 00
00 00 00 00 | f      | (6,28) | {"(6,28)", "(11,1)"}
     12 | (16,8292) |      616 | f      | f      | 2e 00 00 00
00 00 00 00 | f      | (0,27) | {"(0,27)", "(1,13)"}
     13 | (16,8292) |      616 | f      | f      | 2f 00 00 00
00 00 00 00 | f      | (4,17) | {"(4,17)", "(4,21)"}
(13 rows)

```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at `itemoffset` number 1. `ctid` is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the `ctid` field instead. `tids` is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of `ctid` is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of `ctid` stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

`htid` shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match `ctid`, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL `htid` value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page’s “high key”, meaning its data serves as an upper bound on all items appearing on the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see Section 60.4.1. For more details about deduplication and posting lists, see Section 60.4.2.

`bt_page_items(page bytea)` returns `setof record`

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```

test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data,
       dead, htid, tids[0:2] AS some_tids
       FROM bt_page_items(get_raw_page('tenk2_hundred', 5));
 itemoffset | ctid      | itemlen | nulls | vars | data
            | dead | htid | some_tids
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
      1 | (16,1)   |      16 | f     | f     | 30 00 00 00
00 00 00 00 |      |      |
      2 | (16,8292) |     616 | f     | f     | 24 00 00 00
00 00 00 00 | f     | (1,6) | {"(1,6)", "(10,22)"}

```

```

      3 | (16,8292) |      616 | f      | f      | 25 00 00 00
00 00 00 00 | f      | (1,18) | {"(1,18)","(4,22)"}
      4 | (16,8292) |      616 | f      | f      | 26 00 00 00
00 00 00 00 | f      | (4,18) | {"(4,18)","(6,17)"}
      5 | (16,8292) |      616 | f      | f      | 27 00 00 00
00 00 00 00 | f      | (1,2)  | {"(1,2)","(1,19)"}
      6 | (16,8292) |      616 | f      | f      | 28 00 00 00
00 00 00 00 | f      | (2,24) | {"(2,24)","(4,11)"}
      7 | (16,8292) |      616 | f      | f      | 29 00 00 00
00 00 00 00 | f      | (2,17) | {"(2,17)","(11,2)"}
      8 | (16,8292) |      616 | f      | f      | 2a 00 00 00
00 00 00 00 | f      | (0,25) | {"(0,25)","(3,20)"}
      9 | (16,8292) |      616 | f      | f      | 2b 00 00 00
00 00 00 00 | f      | (0,10) | {"(0,10)","(0,14)"}
     10 | (16,8292) |      616 | f      | f      | 2c 00 00 00
00 00 00 00 | f      | (1,3)  | {"(1,3)","(3,9)"}
     11 | (16,8292) |      616 | f      | f      | 2d 00 00 00
00 00 00 00 | f      | (6,28) | {"(6,28)","(11,1)"}
     12 | (16,8292) |      616 | f      | f      | 2e 00 00 00
00 00 00 00 | f      | (0,27) | {"(0,27)","(1,13)"}
     13 | (16,8292) |      616 | f      | f      | 2f 00 00 00
00 00 00 00 | f      | (4,17) | {"(4,17)","(4,21)"}
(13 rows)

```

All the other details are the same as explained in the previous item.

## F.57.4. GIN Functions

`gin_metapage_info(page bytea)` returns record

`gin_metapage_info` returns information about a GIN index metapage. For example:

```

test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index',
0));
-[ RECORD 1 ]-----+-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
n_pending_pages   | 0
n_pending_tuples  | 0
n_total_pages     | 7
n_entry_pages     | 6
n_data_pages      | 0
n_entries         | 693
version           | 2

```

`gin_page_opaque_info(page bytea)` returns record

`gin_page_opaque_info` returns information about a GIN index opaque area, like the page type. For example:

```

test=# SELECT * FROM
  gin_page_opaque_info(get_raw_page('gin_index', 2));
rightlink | maxoff | flags
-----+-----+-----
          5 |      0 | {data,leaf,compressed}
(1 row)

```

`gin_leafpage_items(page bytea)` returns setof record

`gin_leafpage_items` returns information about the data stored in a GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
        FROM gin_leafpage_items(get_raw_page('gin_test_idx',
        2));
 first_tid | nbytes |                               some_tids
-----+-----+-----
(8,41)    |    244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45)   |    248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52)   |    248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59)   |    320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16)  |    376 | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30)  |    376 | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44)  |    197 | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

## F.57.5. Hash Functions

`hash_page_type(page bytea)` returns text

`hash_page_type` returns page type of the given HASH index page. For example:

```
test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
-----
metapage
```

`hash_page_stats(page bytea)` returns setof record

`hash_page_stats` returns information about a bucket or overflow page of a HASH index. For example:

```
test=# SELECT * FROM
 hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]-----+-----
live_items          | 407
dead_items          | 0
page_size           | 8192
free_size           | 8
hasho_prevblkno    | 4096
hasho_nextblkno    | 8474
hasho_bucket        | 0
hasho_flag          | 66
hasho_page_id       | 65408
```

hash\_page\_items(page bytea) returns setof record

hash\_page\_items returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM
  hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset |   ctid   |   data
-----+-----+-----
          1 | (899,77) | 1053474816
          2 | (897,29) | 1053474816
          3 | (894,207)| 1053474816
          4 | (892,159)| 1053474816
          5 | (890,111)| 1053474816
```

hash\_bitmap\_info(index oid, blkno int) returns record

hash\_bitmap\_info shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-----+-----+-----
           65 |          3 | t
```

hash\_metapage\_info(page bytea) returns record

hash\_metapage\_info returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize,
  bmshift,
test-#      maxbucket, highmask, lowmask, ovflpoint, firstfree,
  nmaps, procid,
test-#      regexp_replace(spares::text, '(,0)*}', '}') as
  spares,
test-#      regexp_replace(mapp::text, '(,0)*}', '}') as mapp
test-# FROM hash_metapage_info(get_raw_page('con_hash_index',
  0));
-[ RECORD 1 ]-----
 magic      | 105121344
 version    | 4
 ntuples    | 500500
 ffactor    | 40
 bsize      | 8152
 bmsize     | 4096
 bmshift    | 15
 maxbucket  | 12512
 highmask   | 16383
 lowmask    | 8191
 ovflpoint  | 28
 firstfree  | 1204
 nmaps      | 1
 procid     | 450
 spares     | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,
 508,567,628,704,1193,1202,1204}
```

mapp | {65}

## F.58. passwordcheck

The `passwordcheck` module checks users' passwords whenever they are set with `CREATE ROLE` or `ALTER ROLE`. If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add `'$libdir/passwordcheck'` to `shared_preload_libraries` in `lightdb.conf`, then restart the server.

You can adapt this module to your needs by changing the source code. For example, you can use `CrackLib`<sup>10</sup> to check passwords — this only requires uncommenting two lines in the `Makefile` and rebuilding the module. (We cannot include `CrackLib` by default for license reasons.) Without `CrackLib`, the module enforces a few simple rules for password strength, which you can modify or extend as you see fit.

### Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, LightDB allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 18) than to rely on passwords within the database.

Alternatively, you could modify `passwordcheck` to reject pre-encrypted passwords, but forcing users to set their passwords in clear text carries its own security risks.

## F.59. postgres\_fdw

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external LightDB servers.

The functionality provided by this module overlaps substantially with the functionality of the older `dblink` module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using `CREATE EXTENSION`.
2. Create a foreign server object, using `CREATE SERVER`, to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using `CREATE USER MAPPING`, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using `CREATE FOREIGN TABLE` or `IMPORT FOREIGN SCHEMA`, for each remote table you want to access. The columns of the foreign table must match the referenced

<sup>10</sup> <https://sourceforge.net/projects/cracklib/>

remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, or `COPY`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated later.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

## F.59.1. FDW Options of `postgres_fdw`

### F.59.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in Section 32.1.2, except that these options are not allowed or have special handling:

- `user`, `password` and `sslpassword` (specify these in a user mapping, instead, or use a service file)
- `client_encoding` (this is automatically set from the local server encoding)
- `fallback_application_name` (always set to `postgres_fdw`)
- `sslkey` and `sslcert` - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the `sslcert` or `sslkey` settings.

Only superusers may connect to foreign servers without password authentication, so always specify the `password` option for user mappings belonging to non-superusers.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option `password_required 'false'`, e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the `lightdb` server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the `public` role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc in the unix home directory of the system user the `lightdb` server runs as. They can also use any trust relationship granted by authentication modes like `peer` or `ident` authentication.

### F.59.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote LightDB server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name`

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name`

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name`

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

### F.59.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate`

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost`

This option, which can be specified for a foreign server, is a numeric value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

`fdw_tuple_cost`

This option, which can be specified for a foreign server, is a numeric value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When `use_remote_estimate` is `true`, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is `false`, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running `ANALYZE` on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

### F.59.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions`

This option is a comma-separated list of names of LightDB extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size`

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

### F.59.1.5. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable`

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

### F.59.1.6. Importing Options

`postgres_fdw` is able to import foreign table definitions using `IMPORT FOREIGN SCHEMA`. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate`

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default`

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated`

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null`

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although LightDB does support `CHECK` constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a `CHECK` constraint could lead to hard-to-detect errors in query optimization. So if you wish to import `CHECK` constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of `CHECK` constraints on foreign tables, see `CREATE FOREIGN TABLE`.

Tables or foreign tables which are partitions of some other table are automatically excluded. Partitioned tables are imported, unless they are a partition of some other table. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, this approach should allow access to all the data without creating extra objects.

## F.59.2. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. This connection is kept and re-used for subsequent queries in the same session. However, if multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

## F.59.3. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future LightDB release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

## F.59.4. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

## F.59.5. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see `CREATE FUNCTION`) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for various parameters:

- `TimeZone` is set to `UTC`
- `DateStyle` is set to `ISO`
- `IntervalStyle` is set to `postgres`
- `extra_float_digits` is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

## F.59.6. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to LightDB 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error.

This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-SELECT with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-SELECT.

## F.59.7. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using `CREATE SERVER`. In this example we wish to connect to a LightDB server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname
'foreign_db');
```

A user mapping, defined with `CREATE USER MAPPING`, is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
    OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with `CREATE FOREIGN TABLE`. In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (
    id integer NOT NULL,
    data text
)
    SERVER foreign_server
    OPTIONS (schema_name 'some_schema', table_name
'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of `IMPORT FOREIGN SCHEMA` is preferable to constructing foreign table definitions manually.

Shigeru Hanada <shigeru.hanada@gmail.com>

## F.60. rum

### F.60.1. Introduction

The **rum** module provides access method to work with RUM index. It is based on the GIN access methods code.

GIN index allows to perform fast full text search using `tsvector` and `tsquery` types. But full text search with GIN index has several problems:

- Slow ranking. It is need position information about lexemes to ranking. GIN index doesn't store positions of lexemes. So after index scan we need additional heap scan to retrieve lexemes positions.
- Slow phrase search with GIN index. This problem relates with previous problem. It is need position information to perform phrase search.
- Slow ordering by timestamp. GIN index can't store some related information in index with lexemes. So it is necessary to perform additional heap scan.

RUM solves this problems by storing additional information in posting tree. For example, positional information of lexemes or timestamps.

Drawback of RUM is that it has slower build and insert time than GIN. It is because we need to store additional information besides keys and because RUM uses generic WAL records.

## F.60.2. Common operators and functions

`rum` module provides next operators.

Operator	Returns	Description
<code>tsvector &lt;=&gt; tsquery</code>	float4	Returns distance between <code>tsvector</code> and <code>tsquery</code> .
<code>timestamp &lt;=&gt; timestamp</code>	float8	Returns distance between two timestamps.
<code>timestamp &lt;=  timestamp</code>	float8	Returns distance only for left timestamps.
<code>timestamp  =&gt; timestamp</code>	float8	Returns distance only for right timestamps.

Last three operations also works for types `timestampz`, `int2`, `int4`, `int8`, `float4`, `float8`, `money` and `oid`.

## F.60.3. Operator classes

`rum` provides next operator classes.

### F.60.3.1. `rum_tsvector_ops`

For type: `tsvector`

This operator class stores `tsvector` lexemes with positional information. Supports ordering by `<=>` operator and prefix search. There is the example.

Let us assume we have the table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a',
'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

To create the `rum` index we need create an extension:

```
CREATE EXTENSION rum;
```

Then we can create new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'beautiful | place')
ORDER BY a <=> to_tsquery('english', 'beautiful | place');
```

t	rank
It looks like a beautiful place	8.22467
The situation is most beautiful	16.4493
It is a beautiful	16.4493

(3 rows)

```
SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'place | situation')
ORDER BY a <=> to_tsquery('english', 'place | situation');
```

t	rank
The situation is most beautiful	16.4493
It looks like a beautiful place	16.4493

(2 rows)

### F.60.3.2. rum\_tsvector\_hash\_ops

For type: tsvector

This operator class stores hash of tsvector lexemes with positional information. Supports ordering by <=> operator. But **doesn't** support prefix search.

### F.60.3.3. rum\_TYPE\_ops

For types: int2, int4, int8, float4, float8, money, oid, time, timetz, date, interval, macaddr, inet, cidr, text, varchar, char, bytea, bit, varbit, numeric, timestamp, timestamptz

Supported operations: <, <=, =, >=, > for all types and <=>, <=| and |=> for int2, int4, int8, float4, float8, money, oid, timestamp and timestamptz types.

Supports ordering by <=>, <=| and |=> operators. Can be used with rum\_tsvector\_addon\_ops, rum\_tsvector\_hash\_addon\_ops` andrum\_anyarray\_addon\_ops` operator classes.

### F.60.3.4. rum\_tsvector\_addon\_ops

For type: tsvector

This operator class stores tsvector lexemes with any supported by module field. There is the example.

Let us assume we have the table:

```
CREATE TABLE tsts (id int, t tsvector, d timestamp);
```

```
\copy tstts from 'rum/data/tstts.data'
```

```
CREATE INDEX tstts_idx ON tstts USING rum (t rum_tsvector_addon_ops,
d)
WITH (attach = 'd', to = 't');
```

Now we can execute the following queries:

```
EXPLAIN (costs off)
SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tstts WHERE t @@
'wr&qh' ORDER BY d <=> '2016-05-16 14:21:25' LIMIT 5;
QUERY PLAN
```

```
-----
Limit
->  Index Scan using tstts_idx on tstts
      Index Cond: (t @@ ''wr'' & ''qh''::tsquery)
      Order By: (d <=> 'Mon May 16 14:21:25 2016'::timestamp
without time zone)
(4 rows)
```

```
SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tstts WHERE t @@
'wr&qh' ORDER BY d <=> '2016-05-16 14:21:25' LIMIT 5;
```

```
id | d | ?column?
-----+-----+-----
355 | Mon May 16 14:21:22.326724 2016 | 2.673276
354 | Mon May 16 13:21:22.326724 2016 | 3602.673276
371 | Tue May 17 06:21:22.326724 2016 | 57597.326724
406 | Wed May 18 17:21:22.326724 2016 | 183597.326724
415 | Thu May 19 02:21:22.326724 2016 | 215997.326724
(5 rows)
```

**Warning:** Currently RUM has bogus behaviour when one creates an index using ordering over pass-by-reference additional information. This is due to the fact that posting trees have fixed length right bound and fixed length non-leaf posting items. It isn't allowed to create such indexes.

### F.60.3.5. rum\_tsvector\_hash\_addon\_ops

For type: tsvector

This operator class stores hash of tsvector lexems with any supported by module field.

**Doesn't** support prefix search.

### F.60.3.6. rum\_tsquery\_ops

For type: tsquery

Stores branches of query tree in additional information. For example we have the table:

```
CREATE TABLE query (q tsquery, tag text);

INSERT INTO query VALUES ('supernova & star', 'sn'),
('black', 'color'),
('big & bang & black & hole', 'bang'),
('spiral & galaxy', 'shape'),
('black & hole', 'color');
```

```
CREATE INDEX query_idx ON query USING rum(q);
```

Now we can execute the following fast query:

```
SELECT * FROM query
  WHERE to_tsvector('black holes never exists before we think
about them') @@ q;
   q          | tag
-----+-----
 'black'      | color
 'black' & 'hole' | color
(2 rows)
```

### F.60.3.7. rum\_anyarray\_ops

For type: anyarray

This operator class stores anyarray elements with length of the array. Supports operators &&, @>, <@, =, % operators. Supports ordering by <=> operator. For example we have the table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'),
 ('{1,2,3}'), ('{1,2}'), ('{1}');

CREATE INDEX idx_array ON test_array USING rum (i
rum_anyarray_ops);
```

Now we can execute the query using index scan:

```
SET enable_seqscan TO off;

EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER
BY i <=> '{1}' ASC;
      QUERY PLAN
-----
Index Scan using idx_array on test_array
  Index Cond: (i && '{1}'::smallint[])
  Order By: (i <=> '{1}'::smallint[])
(3 rows)

SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
   i
-----
 {1}
 {1,2}
 {1,2,3}
 {1,2,3,4}
(4 rows)
```

### F.60.3.8. rum\_anyarray\_addon\_ops

For type: anyarray

This operator class stores anyarray elements with any supported by module field.

## F.61. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.61.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
      pH
-----
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
      pH
-----
6.25 .. 6.50
(1 row)
```

### F.61.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F.184 gives an overview of allowed representations; Table F.185 shows some examples.

In Table F.184, `x`, `y`, and `delta` denote floating-point numbers. `x` and `y`, but not `delta`, can be preceded by a certainty indicator.

**Table F.184. `seg` External Representations**

<code>x</code>	Single value (zero-length interval)
<code>x .. y</code>	Interval from <code>x</code> to <code>y</code>
<code>x (+-) delta</code>	Interval from <code>x - delta</code> to <code>x + delta</code>
<code>x ..</code>	Open interval with lower bound <code>x</code>
<code>.. x</code>	Open interval with upper bound <code>x</code>

**Table F.185. Examples of Valid `seg` Input**

<code>5.0</code>	Creates a zero-length segment (a point, if you will)
<code>~5.0</code>	Creates a zero-length segment and records <code>~</code> in the data. <code>~</code> is ignored by <code>seg</code> operations, but is preserved as a comment.
<code>&lt;5.0</code>	Creates a point at 5.0. <code>&lt;</code> is ignored but is preserved as a comment.
<code>&gt;5.0</code>	Creates a point at 5.0. <code>&gt;</code> is ignored but is preserved as a comment.
<code>5 (+-) 0.3</code>	Creates an interval <code>4.7 .. 5.3</code> . Note that the <code>(+-)</code> notation isn't preserved.
<code>50 ..</code>	Everything that is greater than or equal to 50
<code>.. 0</code>	Everything that is less than or equal to 0
<code>1.5e-2 .. 2E-2</code>	Creates an interval <code>0.015 .. 0.02</code>
<code>1 ... 2</code>	The same as <code>1...2</code> , or <code>1 .. 2</code> , or <code>1..2</code> (spaces around the range operator are ignored)

Because the `...` operator is widely used in data sources, it is allowed as an alternative spelling of the `..` operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in `0...23` is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example `5 .. 2`.

### F.61.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

### F.61.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in Table F.186.

**Table F.186. Seg GiST Operators**

Operator	Description
<code>seg &lt;&lt; seg</code>	<code>→ boolean</code>

Operator	Description
	Is the first <code>seg</code> entirely to the left of the second? <code>[a, b] &lt;&lt; [c, d]</code> is true if <code>b &lt; c</code> .
<code>seg &gt;&gt; seg</code> → boolean	Is the first <code>seg</code> entirely to the right of the second? <code>[a, b] &gt;&gt; [c, d]</code> is true if <code>a &gt; d</code> .
<code>seg &amp;&lt; seg</code> → boolean	Does the first <code>seg</code> not extend to the right of the second? <code>[a, b] &amp;&lt; [c, d]</code> is true if <code>b &lt;= d</code> .
<code>seg &amp;&gt; seg</code> → boolean	Does the first <code>seg</code> not extend to the left of the second? <code>[a, b] &amp;&gt; [c, d]</code> is true if <code>a &gt;= c</code> .
<code>seg = seg</code> → boolean	Are the two <code>segs</code> equal?
<code>seg &amp;&amp; seg</code> → boolean	Do the two <code>segs</code> overlap?
<code>seg @&gt; seg</code> → boolean	Does the first <code>seg</code> contain the second?
<code>seg &lt;@ seg</code> → boolean	Is the first <code>seg</code> contained in the second?

(Before LightDB 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `seg`. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use `ORDER BY` with this type.

## F.61.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
lightdb@postgres=> select '10(+-)1'::seg as seg;
      seg
-----
9.0 .. 11          -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

## F.61.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like

to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

## F.62. sepgsql

`sepgsql` is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

### Warning

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See Section F.62.7.

### F.62.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by LightDB. From the perspective of SELinux, this module allows LightDB to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by LightDB.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepgsql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The `SECURITY LABEL` statement allows assignment of a security label to a database object.

### F.62.2. Installation

`sepgsql` can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need `libselinux 2.1.10` or higher and `selinux-policy 3.9.13` or higher (although some distributions may backport the necessary rules into older policy versions).

The `sestatus` command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status:                enabled
SELinuxfs mount:              /selinux
Current mode:                  enforcing
Mode from config file:        enforcing
Policy version:                24
Policy from config file:      targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option `--with-selinux` in your LightDB configure command. Be sure that the `libselinux-devel` RPM is installed at build time.

To use this module, you must include `sepgsql` in the `shared_preload_libraries` parameter in `lightdb.conf`. The module will not function correctly if loaded in any other manner. Once the

module is loaded, you should execute `sepgsql.sql` in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with `sepgsql` functions and security labels installed. Adjust the paths shown as appropriate for your installation:

```
$ export LTDATA=/path/to/data/directory
$ initdb
$ vi $LTDATA/lightdb.conf
  change
    #shared_preload_libraries = ''           # (change
requires restart)
  to
    shared_preload_libraries = 'sepgsql'     # (change
requires restart)
$ for DBNAME in template0 template1 postgres; do
  lightdb --single -F -c exit_on_error=true $DBNAME \
    </usr/local/lightdb-x/share/contrib/sepgsql.sql >/dev/null
done
```

Please note that you may see some or all of the following notifications depending on the particular versions you have of `libselenium` and `selinux-policy`:

```
/etc/selinux/targeted/contexts/sepgsql_contexts: line 33 has
invalid object type db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts: line 36 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 37 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 40 has
invalid object type db_language
```

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

## F.62.3. Regression Tests

Due to the nature of SELinux, running the regression tests for `sepgsql` requires several extra configuration steps, some of which must be done as root. The regression tests will not be run by an ordinary `make check` or `make installcheck` command; you must set up the configuration and then invoke the test script manually. The tests must be run in the `contrib/sepgsql` directory of a configured LightDB build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to `make installcheck` not `make check`.

First, set up `sepgsql` in a working database according to the instructions in Section F.62.2. Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The `sepgsql-regtest` policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file `sepgsql-regtest.te`, which is done using `make` with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on

your system; the path shown below is only an example. (This Makefile is usually supplied by the `selinux-policy-devel` or `selinux-policy` RPM.) Once built, install this policy package using the `semodule` command, which loads supplied policy packages into the kernel. If the package is correctly installed, `semodule -l` should list `sepgsql-regtest` as an available policy package:

```
$ cd .../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07
```

Third, turn on `sepgsql_regression_test_mode`. For security reasons, the rules in `sepgsql-regtest` are not enabled by default; the `sepgsql_regression_test_mode` parameter enables the rules needed to launch the regression tests. It can be turned on using the `setsebool` command:

```
$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode
sepgsql_regression_test_mode --> on
```

Fourth, verify your shell is operating in the `unconfined_t` domain:

```
$ id -z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

See Section F.62.8 for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

```
$ ./test_sepgsql
```

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the `sepgsql` module.

After completing the tests, it's recommended you disable the `sepgsql_regression_test_mode` parameter:

```
$ sudo setsebool sepgsql_regression_test_mode off
```

You might prefer to remove the `sepgsql-regtest` policy entirely:

```
$ sudo semodule -r sepgsql-regtest
```

## F.62.4. GUC Parameters

`sepgsql.permissive` (boolean)

This parameter enables `sepgsql` to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the `lightdb.conf` file or on the server command line.

When this parameter is on, `sepgsql` functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

`sepgsql.debug_audit` (boolean)

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

## F.62.5. Features

### F.62.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label `unlabeled_t`.

Currently, `sepgsql` allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When `sepgsql` is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator's label, the label assigned to the new object's parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

### F.62.5.2. DML Permissions

For tables, `db_table:select`, `db_table:insert`, `db_table:update` or `db_table:delete` are checked for all the referenced target tables depending on the kind of statement; in addition, `db_table:select` is also checked for all the tables that contain columns referenced in the `WHERE` or `RETURNING` clause, as a data source for `UPDATE`, and so on.

Column-level permissions will also be checked for each referenced column. `db_column:select` is checked on not only the columns being read using `SELECT`, but those being referenced in other DML statements; `db_column:update` or `db_column:insert` will also be checked for columns being modified by `UPDATE` or `INSERT`.

For example, consider:

```
UPDATE t1 SET x = 2, y = func1(y) WHERE z = 100;
```

Here, `db_column:update` will be checked for `t1.x`, since it is being updated, `db_column:{select update}` will be checked for `t1.y`, since it is both updated and referenced, and `db_column:select` will be checked for `t1.z`, since it is only referenced. `db_table:{select update}` will also be checked at the table level.

For sequences, `db_sequence:get_value` is checked when we reference a sequence object using `SELECT`; however, note that we do not currently check permissions on execution of corresponding functions such as `lastval()`.

For views, `db_view:expand` will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, `db_procedure: {execute}` will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks `db_procedure: {entrypoint}` permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, `db_schema: search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when `sepgsql` is enabled.

### F.62.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires `create` permission. SELinux will grant or deny this permission based on the client's security label and the proposed security label for the new object. In some cases, additional privileges are required:

- `CREATE DATABASE` additionally requires `getattr` permission for the source or template database.
- Creating a schema object additionally requires `add_name` permission on the parent schema.
- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.
- Creating a function marked as `LEAKPROOF` additionally requires `install` permission. (This permission is also checked when `LEAKPROOF` is set for an existing function.)

When `DROP` command is executed, `drop` will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via `CASCADE`. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires `remove_name` on the schema.

When `ALTER` command is executed, `setattr` will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires `remove_name` permission on the old schema and `add_name` permission on the new one.
- Setting the `LEAKPROOF` attribute on a function requires `install` permission.
- Using `SECURITY LABEL` on an object additionally requires `relabelfrom` permission for the object in conjunction with its old security label and `relabelto` permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only `setattr` should be checked here. This is currently not done due to implementation restrictions.)

## F.62.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or setuid commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```
lightdb@postgres=# CREATE TABLE customer (
                    cid      int primary key,
                    cname    text,
                    credit   text
                    );
CREATE TABLE
lightdb@postgres=# SECURITY LABEL ON COLUMN customer.credit
                   IS 'system_u:object_r:sepgsql_secret_table_t:s0';
SECURITY LABEL
lightdb@postgres=# CREATE FUNCTION show_credit(int) RETURNS text
                   AS 'SELECT regexp_replace(credit, ''-[0-9]+$'', ''-
xxxx'', 'g')
                   FROM customer WHERE cid = $1'
                   LANGUAGE sql;
CREATE FUNCTION
lightdb@postgres=# SECURITY LABEL ON FUNCTION show_credit(int)
                   IS
                   'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';
SECURITY LABEL
```

The above operations should be performed by an administrative user.

```
lightdb@postgres=# SELECT * FROM customer;
ERROR:  SELinux: security policy violation
lightdb@postgres=# SELECT cid, cname, show_credit(cid) FROM
customer;
cid | cname | show_credit
-----+-----+-----
  1 | taro  | 1111-2222-3333-xxxx
  2 | hanako | 5555-6666-7777-xxxx
(2 rows)
```

In this case, a regular user cannot reference `customer.credit` directly, but a trusted procedure `show_credit` allows the user to print the credit card numbers of customers with some of the digits masked out.

## F.62.5.5. Dynamic Domain Transitions

It is possible to use SELinux's dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

```

regression=# select sepysql_getcon();
                sepysql_getcon
-----
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)

regression=# SELECT
  sepysql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c4');
  sepysql_setcon
-----
t
(1 row)

regression=# SELECT
  sepysql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c1023');
ERROR:  SELinux: security policy violation

```

In this example above we were allowed to switch from the larger MCS range `c1 . c1023` to the smaller range `c1 . c4`, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepysql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepysql_setcon()` with `NULL` argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

### F.62.5.6. Miscellaneous

We reject the `LOAD` command across the board, because any module loaded could easily circumvent security policy enforcement.

## F.62.6. Sepysql Functions

Table F.187 shows the available functions.

**Table F.187. Sepysql Functions**

Function	Description
<code>sepysql_getcon()</code> → text	Returns the client domain, the current security label of the client.
<code>sepysql_setcon(text)</code> → boolean	Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts <code>NULL</code> input as a request to transition to the client's original domain.
<code>sepysql_mcstrans_in(text)</code> → text	Translates the given qualified MLS/MCS range into raw format if the <code>mcstrans</code> daemon is running.

Function	Description
<code>sepgsql_mcstrans_out ( text ) → text</code>	Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.
<code>sepgsql_restorecon ( text ) → boolean</code>	Sets up initial security labels for all objects within the current database. The argument may be NULL, or the name of a specfile to be used as alternative of the system default.

## F.62.7. Limitations

### Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.

### Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

### Row-level access control

LightDB supports row-level access, but `sepgsql` does not.

### Covert channels

`sepgsql` does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

### Fedora SELinux FAQ<sup>13</sup>

This document answers frequently asked questions about SELinux. It focuses primarily on Fedora, but is not limited to Fedora.

## F.62.9. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

## F.63. spi

<sup>11</sup> <https://wiki.postgresql.org/wiki/SEPostgreSQL>

<sup>12</sup> [https://access.redhat.com/documentation/en-us/red\\_hat\\_enterprise\\_linux/7/html/selinux\\_users\\_and\\_administrators\\_guide/index](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/7/html/selinux_users_and_administrators_guide/index)

<sup>13</sup> [https://fedoraproject.org/wiki/SELinux\\_FAQ](https://fedoraproject.org/wiki/SELinux_FAQ)

The `spi` module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

## F.63.1. `refint` — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

There are examples in `refint.example`.

## F.63.2. `autoinc` — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

## F.63.3. `insert_username` — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

## F.63.4. `moddatetime` — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

## F.64. `sslinfo`

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to LightDB. The module is useless (most functions will return `NULL`) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-openssl`.

### F.64.1. Functions Provided

`ssl_is_used()` returns `boolean`

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version()` returns `text`

Returns the name of the protocol used for the SSL connection (e.g., `TLSv1.0`, `TLSv1.1`, or `TLSv1.2`).

`ssl_cipher()` returns `text`

Returns the name of the cipher used for the SSL connection (e.g., `DHE-RSA-AES256-SHA`).

`ssl_client_cert_present()` returns `boolean`

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns `numeric`

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns `text`

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the `SQL_ASCII` encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

```
commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress
```

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns text

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

## F.65. system\_stats

*system\_stats* is a LightDB extension that provides functions to access system level statistics that can be used for monitoring.

### F.65.1. Security

Due to the nature of the information returned by these functions, access is restricted to superusers and members of the `monitor_system_stats` role which will be created when the extension is installed. To allow users to access the functions without granting them superuser access, add them to the `monitor_system_stats` role. For example:

```
GRANT monitor_system_stats to nagios;
```

### F.65.2. Functions

The following functions are provided to fetch system level statistics for all platforms.

#### F.65.2.1. pg\_sys\_os\_info

This interface allows the user to get operating system statistics.

#### F.65.2.2. pg\_sys\_cpu\_info

This interface allows the user to get CPU information.

#### F.65.2.3. pg\_sys\_cpu\_usage\_info

This interface allows the user to get CPU usage information. Values are a percentage of time spent by CPUs for all operations.

#### F.65.2.4. pg\_sys\_memory\_info

This interface allows the user to get memory usage information. All the values are in bytes.

#### F.65.2.5. pg\_sys\_io\_analysis\_info

This interface allows the user to get an I/O analysis of block devices.

#### F.65.2.6. pg\_sys\_disk\_info

This interface allows the user to get the disk information.

#### F.65.2.7. pg\_sys\_load\_avg\_info

This interface allows the user to get the average load of the system over 1, 5, 10 and 15 minute intervals.

#### F.65.2.8. pg\_sys\_process\_info

This interface allows the user to get process information.

#### F.65.2.9. pg\_sys\_network\_info

This interface allows the user to get network interface information.

## **F.65.2.10. pg\_sys\_cpu\_memory\_by\_process**

This interface allows the user to get the CPU and memory information for each process ID.

## **F.65.3. Detailed output of each functions**

### **F.65.3.1. pg\_sys\_os\_info**

- Name
- Version
- Host name
- Domain name
- Handle count
- Process count
- Thread count
- Architecture
- Last bootup time
- Uptime in seconds

### **F.65.3.2. pg\_sys\_cpu\_info**

- Vendor
- Description
- Model name
- Processor type
- Logical processor
- Physical processor
- Number of cores
- Architecture
- Clock speed in hz
- CPU type
- CPU family
- Byte order
- L1d cache size
- L1i cache size
- L2 cache size
- L3 cache size

### **F.65.3.3. pg\_sys\_cpu\_usage\_info**

- Percent time spent in processing usermode normal process
- Percent time spent in processing usermode niced process
- Percent time spent in kernel mode process
- Percent time spent in idle mode
- Percent time spent in io completion
- Percent time spent in servicing interrupt
- Percent time spent in servicing software interrupt
- Percent user time spent
- Percent processor time spent
- Percent privileged time spent
- Percent interrupt time spent

### **F.65.3.4. pg\_sys\_memory\_info**

- Total memory
- Used memory
- Free memory

- Total swap memory
- Used swap memory
- Free swap memory
- Total cache memory
- Total kernel memory
- Kernel paged memory
- Kernel non paged memory
- Total page file
- Available page file

### **F.65.3.5. pg\_sys\_io\_analysis\_info**

- Block device name
- Total number of reads
- Total number of writes
- Read bytes
- Written bytes
- Time spent in milliseconds for reading
- Time spent in milliseconds for writing

### **F.65.3.6. pg\_sys\_disk\_info**

- File system of the disk
- File system type
- Mount point for the file system
- Drive letter
- Drive type
- Total space in bytes
- Used space in bytes
- Available space in bytes
- Number of total inodes
- Number of used inodes
- Number of free inodes

### **F.65.3.7. pg\_sys\_load\_avg\_info**

- 1 minute load average
- 5 minute load average
- 10 minute load average
- 15 minute load average

### **F.65.3.8. pg\_sys\_process\_info**

- Number of total processes
- Number of running processes
- Number of sleeping processes
- Number of stopped processes
- Number of zombie processes

### **F.65.3.9. pg\_sys\_network\_info**

- Name of the interface\_name
- ipv4 address of the interface
- Number of total bytes transmitted
- Number of total packets transmitted
- Number of transmit errors by this network device
- Number of packets dropped during transmission
- Number of total bytes received

- Number of total packets received
- Number of receive errors by this network device
- Number of packets dropped by this network device
- Interface speed in mbps

### F.65.3.10. pg\_sys\_cpu\_memory\_by\_process

- PID of the process
- Process name
- CPU usage in bytes
- Memory usage in bytes
- Total memory used in bytes

## F.66. tablefunc

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.66.1. Functions Provided

Table F.188 summarizes the functions provided by the `tablefunc` module.

**Table F.188. tablefunc Functions**

Function	Description
<code>normal_rand ( numvals integer, mean float8, stddev float8 )</code>	<code>→ setof float8</code> Produces a set of normally distributed random values.
<code>crosstab ( sql text )</code>	<code>→ setof record</code> Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query.
<code>crosstabN ( sql text )</code>	<code>→ setof table_crosstab_N</code> Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below.
<code>crosstab ( source_sql text, category_sql text )</code>	<code>→ setof record</code> Produces a “pivot table” with the value columns specified by a second query.
<code>crosstab ( sql text, N integer )</code>	<code>→ setof record</code> Obsolete version of <code>crosstab ( text )</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query.
<code>connectby ( relname text, keyid_fld text, parent_keyid_fld text [, orderby_fld text ], start_with text, max_depth integer [, branch_delim text ] )</code>	<code>→ setof record</code> Produces a representation of a hierarchical tree structure.

#### F.66.1.1. normal\_rand

`normal_rand(int numvals, float8 mean, float8 stddev)` returns set of float8

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

*numvals* is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
      normal_rand
-----
 1.56556322244898
 9.10040991424657
 5.36957140345079
-0.369151492880995
 0.283600703686639
      .
      .
      .
 4.82992125404908
 9.71308014517282
 2.49639286969028
(1000 rows)
```

### F.66.1.2. `crosstab(text)`

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1  val11
row1  val12
row1  val13
...
row2  val21
row2  val22
row2  val23
...
```

which we wish to display like

```
row1  val11  val12  val13  ...
row2  val21  val22  val23  ...
...
```

The `crosstab` function takes a text parameter that is a SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The *sql* parameter is a SQL statement that produces the source set of data. This statement must return one *row\_name* column, one *category* column, and one *value* column. *N* is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

row_name	cat	value
row1	cat1	val1
row1	cat2	val2
row1	cat3	val3
row1	cat4	val4
row2	cat1	val5
row2	cat2	val6
row2	cat3	val7
row2	cat4	val8

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text,
category_2 text);
```

This example produces a set something like:

row_name	<= value columns ==>	
	category_1	category_2
row1	val1	val2
row2	val5	val6

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N` `value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1, 2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att1','val5');
```

```

INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att4','val8');

SELECT *
FROM crosstab(
  'select rowid, attribute, value
   from ct
   where attribute = 'att2' or attribute = 'att3'
   order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3
text);

 row_name | category_1 | category_2 | category_3
-----+-----+-----+-----
 test1   | val2       | val3       |
 test2   | val6       | val7       |
(2 rows)

```

You can avoid always having to write out a FROM clause to define the output columns, by setting up a custom crosstab function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required FROM clause in a view definition.

### Note

See also the `\crosstabview` command in `ltsql`, which provides functionality similar to `crosstab()`.

## F.66.1.3. `crosstabN(text)`

```
crosstabN(text sql)
```

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```

CREATE TYPE tablefunc_crosstab_N AS (
  row_name TEXT,
  category_1 TEXT,
  category_2 TEXT,
  .
  .
  .
  category_N TEXT
);

```

Thus, these functions can be used directly when the input query produces `row_name` and value columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```

SELECT *
FROM crosstab3(
  'select rowid, attribute, value
   from ct
   where attribute = 'att2' or attribute = 'att3'
   order by 1,2');

```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one text parameter and returning setof `your_type_name`, but linking to the same underlying `crosstab C` function. For example, if your source data produces row names that are text, and values that are float8, and you want 5 value columns:

```

CREATE TYPE my_crosstab_float8_5_cols AS (
  my_row_name text,
  my_category_1 float8,
  my_category_2 float8,
  my_category_3 float8,
  my_category_4 float8,
  my_category_5 float8
);

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
  RETURNS setof my_crosstab_float8_5_cols
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

```

- Use OUT parameters to define the return type implicitly. The same example could also be done this way:

```

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
  IN text,
  OUT my_row_name text,
  OUT my_category_1 float8,
  OUT my_category_2 float8,
  OUT my_category_3 float8,
  OUT my_category_4 float8,
  OUT my_category_5 float8)
  RETURNS setof record
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

```

### F.66.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more

“extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, `source_sql` might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

row_name	extra_col	cat	value
row1	extra1	cat1	val1
row1	extra1	cat2	val2
row1	extra1	cat4	val4
row2	extra2	cat1	val5
row2	extra2	cat2	val6
row2	extra2	cat3	val7
row2	extra2	cat4	val8

`category_sql` is a SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. `category_sql` might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
```

```
cat
-----
cat1
cat2
cat3
cat4
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3
text, cat4 text);
```

This will produce a result something like:

row_name	extra	<== value columns ==>	cat1	cat2	cat3	cat4
row1	extra1	val1	val2			val4
row2	extra2	val5	val6	val7		val8

The `FROM` clause must define the proper number of output columns of the proper data types. If there are  $N$  columns in the `source_sql` query's result, the first  $N-2$  of them must match up with the first  $N-2$  output columns. The remaining output columns must have the type of the last column of the `source_sql` query's result, and there must be exactly as many of them as there are rows in the `category_sql` query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching `category` values. If a row's `category` does not match any output of the

*category\_sql* query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the *source\_sql* query should always specify `ORDER BY 1` to ensure that values with the same *row\_name* are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the *category\_sql* query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as (
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
  "Oct" int,
  "Nov" int,
  "Dec" int
);

```

year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct
2007	1000	1500					500			
	1500	2000								
2008	1000									

(2 rows)

```
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val
text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March
2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March
2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01
March 2003');
```

```

INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
(
  'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
  'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
AS
(
  rowid text,
  rowdt timestamp,
  temperature int4,
  test_result text,
  test_startdate timestamp,
  volts float8
);
rowid |          rowdt          | temperature | test_result |
test_startdate | volts
-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS        |
          |          2.6987
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL        | Sat
Mar 01 00:00:00 2003 |          3.1234
(2 rows)

```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of crosstab is named `crosstab_hash`.

### F.66.1.5. connectby

```

connectby(text relname, text keyid_fld, text parent_keyid_fld
          [, text orderby_fld ], text start_with, int max_depth
          [, text branch_delim ])

```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.189 explains the parameters.

**Table F.189. connectby Parameters**

Parameter	Description
<i>relname</i>	Name of the source relation
<i>keyid_fld</i>	Name of the key field
<i>parent_keyid_fld</i>	Name of the parent-key field
<i>orderby_fld</i>	Name of the field to order siblings by (optional)
<i>start_with</i>	Key value of the row to start at
<i>max_depth</i>	Maximum depth to descend to, or zero for unlimited depth
<i>branch_delim</i>	String to separate keys with in branch output (optional)

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start\_with* value must be entered as a text string, regardless of the type of the key field.

The *connectby* function is declared to return *setof record*, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid',
    'pos', 'row2', 0, '~')
    AS t(keyid text, parent_keyid text, level int, branch text, pos
    int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type *integer*. If a *branch\_delim* parameter was given, the next output column is the branch display and must be of type *text*. Finally, if an *orderby\_fld* parameter was given, the last output column is a serial number, and must be of type *integer*.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified *branch\_delim* string. If no branch display is wanted, omit both the *branch\_delim* parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the *orderby\_fld* parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if *orderby\_fld* is specified.

The parameters representing table and field names are copied as-is into the SQL queries that *connectby* generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the *branch\_delim* string not appear in any key values, else *connectby* may incorrectly report an infinite-recursion error. Note that if *branch\_delim* is not provided, a default value of ~ is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos
    int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);

-- with branch, without orderby_fld (order of results is not
-- guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid',
    'row2', 0, '~')
    AS t(keyid text, parent_keyid text, level int, branch text);
keyid | parent_keyid | level |          branch
-----+-----+-----+-----
row2  |              |      0 | row2
row4  | row2         |      1 | row2~row4
```

```

row6 | row4          |      2 | row2~row4~row6
row8 | row6          |      3 | row2~row4~row6~row8
row5 | row2          |      1 | row2~row5
row9 | row5          |      2 | row2~row5~row9
(6 rows)

```

```

-- without branch, without orderby_fld (order of results is not
guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid',
'row2', 0)

```

```

AS t(keyid text, parent_keyid text, level int);

```

```

keyid | parent_keyid | level
-----+-----+-----

```

```

row2 |          |      0
row4 | row2     |      1
row6 | row4     |      2
row8 | row6     |      3
row5 | row2     |      1
row9 | row5     |      2
(6 rows)

```

```

-- with branch, with orderby_fld (notice that row5 comes before
row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid',
'pos', 'row2', 0, '~')

```

```

AS t(keyid text, parent_keyid text, level int, branch text, pos
int);

```

```

keyid | parent_keyid | level |          branch          | pos
-----+-----+-----+-----+-----

```

```

row2 |          |      0 | row2                    | 1

row8 | row6     |      3 | 6
(6 rows)

```

## F.66.2. Author

Joe Conway

## F.67. tcn

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER trigger FOR EACH ROW`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test=# (
test(#   a int not null,
test(#   b date not null,
test(#   c text,
test(#   primary key (a, b)
test(# );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test=# after insert or update or delete on tcndata
test=# for each row execute function
  triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test=#                               (1, date '2012-12-23',
  'another'),
test=#                               (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload
  ""tcndata",I,"a"='1',"b"='2012-12-22'" received from server
  process with PID 22770.
Asynchronous notification "tcn" with payload
  ""tcndata",I,"a"='1',"b"='2012-12-23'" received from server
  process with PID 22770.
Asynchronous notification "tcn" with payload
  ""tcndata",I,"a"='2',"b"='2012-12-23'" received from server
  process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload
  ""tcndata",U,"a"='1',"b"='2012-12-22'" received from server
  process with PID 22770.
Asynchronous notification "tcn" with payload
  ""tcndata",U,"a"='1',"b"='2012-12-23'" received from server
  process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
```

```
Asynchronous notification "tcn" with payload
""tcndata",D,"a"='1',"b"='2012-12-22'" received from server
process with PID 22770.
```

## F.68. test\_decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
lightdb@postgres=# SELECT * FROM
pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
   lsn   | xid | data
-----+-----
0/16D30F8 | 691 | BEGIN
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2
data[text]: 'arg'
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3
data[text]: 'demo'
0/16D32A0 | 691 | COMMIT
0/16D32D8 | 692 | BEGIN
0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
0/16D3398 | 692 | COMMIT
(8 rows)
```

## F.69. tsm\_system\_rows

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.69.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

## F.70. `tsm_system_time`

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.70.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

## F.71. `tsvector2`

Extended `tsvector` type for LightDB. It was implemented to provide better compression and to remove 1MB size limitation of original `tsvector` type.

It could be used as transparent replacement of original `tsvector` and supports all its functions, operators and index types. Functions that contain `tsvector` in their names have been changed to `tsvector2`. Full list of these functions specified below.

Refer to LightDB documentation to get details about `tsvector`. They can be also applied to `tsvector2`.

### F.71.1. `tsvector2` specific functions

- `to_tsvector2` (from `text`, `json`, `jsonb` types)
- `array_to_tsvector2`
- `tsvector2_to_array`

- `tsvector2_stat` (should be used instead of `ts_stat`)
- `jsonb_to_tsvector2`
- `json_to_tsvector2`
- `tsvector2_update_trigger`
- `tsvector2_update_trigger_column`

## F.71.2. Common functions that could be safely used on both types

- `strip`
- `unnest`
- `length`
- `setweight`
- `ts_rank`
- `ts_rank_cd`
- `ts_delete`
- `ts_filter`

## F.72. unaccent

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the thesaurus dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.72.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$_SHAREDIR/tsearch_data/` (where `$_SHAREDIR` means the LightDB installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

```
À      A
Á      A
Â      A
Ã      A
Ä      A
Å      A
Æ      AE
```

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.

- Actually, each “character” can be any string not containing whitespace, so unaccent dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- As with other LightDB text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$SHAREDIR/tsearch_data/` when the unaccent module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, `Æ` to `AE`).

## F.72.2. Usage

Installing the unaccent extension creates a text search template unaccent and a dictionary unaccent based on it. The unaccent dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
 ts_lexize
-----
 {Hotel}
(1 row)
```

Here is an example showing how to insert the unaccent dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
 to_tsvector
-----
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@
 to_tsquery('fr','Hotels');
 ?column?
-----
 t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la
 Mer',to_tsquery('fr','Hotels'));
 ts_headline
-----
 <b>Hôtel</b> de la Mer
```

(1 row)

## F.72.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary, ] string text)` returns `text`

If the `dictionary` argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

## F.73. uuid-oss

The `uuid-oss` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core LightDB. See Section 9.14 for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.73.1. uuid-oss Functions

Table F.190 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

**Table F.190. Functions for UUID Generation**

Function	Description
<code>uuid_generate_v1()</code> → <code>uuid</code>	Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.
<code>uuid_generate_v1mc()</code> → <code>uuid</code>	Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.
<code>uuid_generate_v3(namespace uuid, name text)</code> → <code>uuid</code>	Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code> () functions shown in Table F.191. (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example:

Function	Description
	<pre>SELECT uuid_generate_v3(uuid_ns_url(), 'www.hs.net/lightdb');</pre> <p>The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.</p>
<code>uuid_generate_v4 ()</code> → <code>uuid</code>	Generates a version 4 UUID, which is derived entirely from random numbers.
<code>sys_guid ()</code> → <code>uuid</code>	Generates a version 4 UUID, which is derived entirely from random numbers. Equivalent with function <code>uuid_generate_v4</code> .
<code>uuid_generate_v5 ( namespace uuid, name text )</code> → <code>uuid</code>	Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.

**Table F.191. Functions Returning UUID Constants**

Function	Description
<code>uuid_nil ()</code> → <code>uuid</code>	Returns a “nil” UUID constant, which does not occur as a real UUID.
<code>uuid_ns_dns ()</code> → <code>uuid</code>	Returns a constant designating the DNS namespace for UUIDs.
<code>uuid_ns_url ()</code> → <code>uuid</code>	Returns a constant designating the URL namespace for UUIDs.
<code>uuid_ns_oid ()</code> → <code>uuid</code>	Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in LightDB.)
<code>uuid_ns_x500 ()</code> → <code>uuid</code>	Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.

## F.73.2. Author

Peter Eisentraut <peter\_e@gmx.net>

## F.74. wal2sql

The `wal2sql` is an output extension for logical decoding. It means that the extension have access to tuples produced by INSERT and UPDATE. Also, UPDATE/DELETE old row versions can be accessed depending on the configured replica identity. Changes can be consumed using the streaming protocol (logical replication slots) or by a special SQL API.

format version 1 produces a JSON object per transaction. All of the new/old tuples are available in the JSON object. Also, there are options to include properties such as transaction timestamp, schema-qualified, data types, and transaction ids.

format version 2 produces a JSON object per tuple. Optional JSON object for beginning and end of transaction. Also, there are a variety of options to include properties.

## F.74.1. Configuration

You need to set up at least parameters at `lightdb.conf`

```
# lightdb.conf
wal_level = logical
```

## F.74.2. Configuration Parameters

`include-transaction` (boolean)

emit records denoting the start and end of each transaction. Default is true.

`include-xids` (boolean)

add xid to each changeset. Default is false.

`include-timestamp` (boolean)

add timestamp to each changeset. Default is false.

`include-pk` (boolean)

add primary key information as pk. Column name and data type is included. Default is false.

`include-origin` (boolean)

add origin of a piece of data. Default is false.

`include-schemas` (boolean)

add schema to each change. Default is true.

`include-types` (boolean)

add type to each change. Default is true.

`include-type-oids` (boolean)

add type oids. Default is false.

`include-typmod` (boolean)

add modifier to types that have it (eg. `varchar(20)` instead of `varchar`). Default is true.

`include-domain-data-type` (boolean)

replace domain name with the underlying data type. Default is false.

`include-column-positions` (boolean)

add column position (`pg_attribute.attnum`). Default is false.

`include-not-null` (boolean)

add not null information as `columnoptionals`. Default is false.

`include-default` (boolean)

add default expression. Default is false.

`pretty-print` (boolean)

add spaces and indentation to JSON structures. Default is false.

`write-in-chunks` (boolean)

write after every change instead of every changeset. Only used when `format-version` is 1. Default is false.

`include-lsn` (boolean)

add nextlsn to each changeset. Default is false.

`actions` (boolean)

define which operations will be sent. Default is all actions (insert, update, delete, and truncate). However, if you are using `format-version` 1, truncate is not enabled (backward compatibility).

`filter-origins` (boolean)

exclude changes from the specified origins. Default is empty which means that no origin will be filtered. It is a comma separated value.

`filter-tables` (boolean)

exclude rows from the specified tables. Default is empty which means that no table will be filtered. It is a comma separated value. The tables should be schema-qualified. `*.foo` means table foo in all schemas and `bar.*` means all tables in schema bar. Special characters (space, single quote, comma, period, asterisk) must be escaped with backslash. Schema and table are case-sensitive. Table "public"."Foo bar" should be specified as `public.Foo\ bar`.

`add-tables` (boolean)

include only rows from the specified tables. Default is all tables from all schemas. It has the same rules from `filter-tables`.

`filter-msg-prefixes` (boolean)

exclude messages if prefix is in the list. Default is empty which means that no message will be filtered. It is a comma separated value.

`add-msg-prefixes` (boolean)

include only messages if prefix is in the list. Default is all prefixes. It is a comma separated value. `wal2sql` applies `filter-msg-prefixes` before this parameter.

`format-version` (integer)

defines which format to use. Default is 1.

## F.74.3. Examples of Parameters

There are two ways to obtain the changes (JSON objects) from `wal2sql` plugin: calling functions via `ltdts_recvlogical` or SQL.

### F.74.3.1. `ltdts_recvlogical`

Besides the configuration above, it is necessary to configure a replication connection to use `ltdts_recvlogical`.

Add a replication connection rule at `lt_hba.conf`

```
                local    mydatabase    myuser
trust
```

Also, set `max_wal_senders` at `lightdb.conf`:

```
max_wal_senders = 1
```

A restart is necessary if you changed `max_wal_senders`. You are ready to try `wal2sql`. In one terminal:

```
                # create a logical replication slot name as
test_oracle_slot
                ltdts_recvlogical -d postgres --slot=test_oracle_slot
--create-slot -P wal2sql

                # delete a logical replication slot
                ltdts_recvlogical -d postgres --slot=test_oracle_slot
--drop-slot

                # print output in the first terminal
                ltdts_recvlogical -d postgres --slot test_oracle_slot
--start -o pretty-print=1 -o add-msg-prefixes=wal2sql -f -

                # forward output to oracle#
                ltdts_recvlogical --tnsname=TEST --oracle-
username=scott --oracle-password=tiger --start --
slot=test_oracle_slot -o include-types=false
                -o include-type-oids=true -d postgres -h 10.20.30.193 -
p 9999 -f debug.dat
```

## F.74.3.2. SQL

Save the following code and execute it

```
                CREATE TABLE table3_with_pk (a SERIAL, b VARCHAR(30), c
TIMESTAMP NOT NULL, PRIMARY KEY(a, c));
                CREATE TABLE table3_without_pk (a SERIAL, b
NUMERIC(5,2), c TEXT);

                SELECT 'init' FROM
pg_create_logical_replication_slot('test_slot', 'wal2sql');

                BEGIN;
                INSERT INTO table3_with_pk (b, c) VALUES('Backup and
Restore', now());
                INSERT INTO table3_with_pk (b, c) VALUES('Tuning',
now());
                INSERT INTO table3_with_pk (b, c) VALUES('Replication',
now());
                SELECT pg_logical_emit_message(true, 'wal2sql', 'this
message will be delivered');
```

```

DELETE FROM table3_with_pk WHERE a < 3;
SELECT pg_logical_emit_message(false, 'wal2sql', 'this
non-transactional message will be delivered even if you rollback
the transaction');

INSERT INTO table3_without_pk (b, c) VALUES(2.34,
'Tapir');
-- it is not added to stream because there isn't a pk
or a replica identity
UPDATE table3_without_pk SET c = 'Anta' WHERE c =
'Tapir';
COMMIT;

SELECT data FROM
pg_logical_slot_get_changes('test_slot', NULL, NULL, 'format-
version', '2', 'add-msg-prefixes', 'wal2sql');
SELECT 'stop' FROM
pg_drop_replication_slot('test_slot');

DROP TABLE table3_with_pk;
DROP TABLE table3_without_pk;

```

## F.74.4. Note

1. wal2sql is not supported on LoongArch<sup>14</sup>.
2. In high availability please start `ltdts_logicalrepl_copier.sh` to copy slot from primary to standby.
3. In high availability when failover occur, please restart new primary LightDB to let slot work.

## F.75. xml2

The `xml2` module provides XPath querying and XSLT functionality.

### F.75.1. Deprecation Notice

From LightDB 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of LightDB in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to [pgsql-hackers@lists.postgresql.org](mailto:pgsql-hackers@lists.postgresql.org) so that the deficiency can be addressed.

### F.75.2. Description of Functions

Table F.192 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

**Table F.192. `xml2` Functions**

Function	Description
<code>xml_valid</code>	<code>( document text ) → boolean</code>

<sup>14</sup> <https://www.loongson.cn/>

Function	Description
	Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard LightDB function <code>xml_is_well_formed()</code> . The name <code>xml_valid()</code> is technically incorrect since validity and well-formedness have different meanings in XML.)
<code>xpath_string ( document text, query text ) → text</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>text</code> .
<code>xpath_number ( document text, query text ) → real</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>real</code> .
<code>xpath_bool ( document text, query text ) → boolean</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>boolean</code> .
<code>xpath_nodeSet ( document text, query text, toptag text, itemtag text ) → text</code>	Evaluates the query on the document and wraps the result in XML tags. If the result is multivalued, the output will look like:  <pre>&lt;toptag&gt; &lt;itemtag&gt;Value 1 which could be an XML fragment&lt;/itemtag&gt; &lt;itemtag&gt;Value 2....&lt;/itemtag&gt; &lt;/toptag&gt;</pre> <p>If either <code>toptag</code> or <code>itemtag</code> is an empty string, the relevant tag is omitted.</p>
<code>xpath_nodeSet ( document text, query text, itemtag text ) → text</code>	Like <code>xpath_nodeSet ( document, query, toptag, itemtag )</code> but result omits <code>toptag</code> .
<code>xpath_nodeSet ( document text, query text ) → text</code>	Like <code>xpath_nodeSet ( document, query, toptag, itemtag )</code> but result omits both tags.
<code>xpath_list ( document text, query text, separator text ) → text</code>	Evaluates the query on the document and returns multiple values separated by the specified separator, for example <code>Value 1, Value 2, Value 3</code> if <code>separator</code> is <code>,</code> .
<code>xpath_list ( document text, query text ) → text</code>	This is a wrapper for the above function that uses <code>,</code> as the separator.

### F.75.3. `xpath_table`

`xpath_table ( text key, text document, text relation, text xpaths, text criteria )` returns `setof record`

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F.193.

**Table F.193. `xpath_table` Parameters**

Parameter	Description
<code>key</code>	the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record

Parameter	Description
	from which each output row came (see note below about multiple values)
<i>document</i>	the name of the field containing the XML document
<i>relation</i>	the name of the table or view containing the documents
<i>xpaths</i>	one or more XPath expressions, separated by
<i>criteria</i>	the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation

These parameters (except the XPath strings) are just substituted into a plain SQL `SELECT` statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this `SELECT` needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a `FROM` expression, with an `AS` clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title
text);
```

The `AS` clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be `NULL`.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use `LightDB` input functions to transform it into an integer (or whatever type the `AS` clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling `SELECT` statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|/article/author/@id',
                'xpath_string(article_xml, '/article/@date') >
                ''2003-03-20'' ')
AS t(article_id integer, title text, author_id integer),
tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.75.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the `key` field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
  id int PRIMARY KEY,
  xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
  xpath_table('id','xml','test',
    '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/
doc/line/c',
    'true')
  AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int,
    val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

id	doc_num	line_num	val1	val2	val3
1	C1	L1	1	2	3
1		L2	11	22	33

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
    '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
    'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3
int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

id	line_num	val1	val2	val3	doc_num
1	L1	1	2	3	C1
1	L2	11	22	33	C1

(2 rows)

## F.75.4. XSLT Functions

The following functions are available if libxslt is installed:

### F.75.4.1. `xslt_process`

```
xslt_process(text document, text stylesheet, text paramlist)
returns text
```

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

## F.75.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. ([www.torchbox.com](http://www.torchbox.com)). It has the same BSD license as LightDB.

## F.76. zhparser

`zhparser` is a LightDB extension for full-text search of Chinese language (Mandarin Chinese). It implements a Chinese language parser base on the Simple Chinese Word Segmentation (SCWS).

### F.76.1. CONFIGURATION

These options are used to control dictionary loading behavior and word segmentation behavior. None of these options is required and are false by default (that is, if these options are not set in the configuration file, `zhparser` behaves the same as setting the following options to false).

Ignore all special symbols such as punctuation: `zhparser.punctuation_ignore = f`

Idle words are automatically grouped in two-word word segmentation: `zhparser.seg_with_duality = f`

Load all dictionaries into memory: `zhparser.dict_in_memory = f`

Short word compound: `zhparser.multi_short = f`

Hash binary compound: `zhparser.multi_duality = f`

Important word compound: `zhparser.multi_zmain = f`

Set `zhparser` non stop words: See `lightdb_tsearch_non_stopwords` for more information

In addition to the dictionaries shipped with `zhparser`, you can add custom dictionaries, which take precedence over native dictionaries. The file must be stored in the `share/postgresql/tsearch_data`

directory. zhparser determines the dictionary format based on the file extension. The.txt extension means that the dictionary is in text format, and the.xdb extension means that the dictionary is in XDB format. Multiple files are separated by commas, and dictionaries are categorized in descending order of priority, such as:

```
zhparser.extra_dicts = 'dict_extra.txt,mydict.xdb'
```

Note: The zhparser.extra\_dicts and zhparser.dict\_in\_memory options need to be set before backend starts (can be changed in configuration file and reload, after which a new connection takes effect), other options can be set to take effect at any time in session.

## F.76.2. EXAMPLE

```
-- make test configuration using parser

CREATE TEXT SEARCH CONFIGURATION testzhcfg (PARSER =
zhparser);

-- add token mapping

ALTER TEXT SEARCH CONFIGURATION testzhcfg ADD MAPPING
FOR n,v,a,i,e,l WITH simple;

-- ts_parse

SELECT * FROM ts_parse('zhparser', 'hello world! 2010##
##### #2011#####
#####');

-- test to_tsvector

SELECT to_tsvector('testzhcfg', '#####
#####>#####"#####2011#####2012#####
#####');

-- test to_tsquery

SELECT to_tsquery('testzhcfg', '#####');

-- test lightdb_tsearch_non_stopwords

SET lightdb_tsearch_non_stopwords = '1';
ERROR:  invalid value for parameter
"lightdb_tsearch_non_stopwords": "1"
DETAIL:  lightdb_tsearch_non_stopwords not support '1'
as non stopword.

SET lightdb_tsearch_non_stopwords = '@:_-';
SELECT to_tsvector('testzhcfg', '#####this is from
lt_hs_tab table #####logged at 2020-12-21 ##### 00:22:32,
username=zjh&pwd=balabala');

to_tsvector
```

```

'00:22:32':16 '2020-12-21':13 'at':12 'from':5 'is':4

## F.76.3. Custom dictionary

\*\* TXT dictionary is currently compatible with CLI/SCws\_gen\_dict used text dictionary) \*\*

- One entry per line, Comments starting with a # or semicolon are ignored and skipped

Each line consists of 4 fields, which are successively "word "(composed of Chinese characters or less than 3 letters), "TF", "IDF" and" part of speech ". The fields are separated by Spaces or tabs. There is no limit on the number of fields, and they can be aligned to beautify themselves

Except for "word", other fields can be ignored. If omitted, TF and IDF default to 1.0 and the part of speech is "@"

TXT library dynamic loading (internal monitoring file modification time is automatically converted into XDB stored in the system temporary directory), it is recommended that TXT dictionary not too large

To delete words, please set the part of speech to "!", the word is set to invalid, even if it exists in other core libraries

Note: 1. The format of the custom dictionary can be TXT or binary XDB format. The XDB format is more efficient and suitable for large dictionaries. You can use the built-in SCWS tool scWS-Gen-dict to convert text dictionaries to XDB format. 2. The default zhparser dictionary is Simplified Chinese.

## F.76.4. Custom dictionary 2.1

\*\* Custom dictionary 2.1 adds the portability of custom dictionary and is compatible with features provided by 1.0 \*\*

Custom dictionary require superuser privileges. Custom dictionary are database-level (not instance). Each database has its own custom participle and is stored under the data directory base/ database ID (version 2.0 is stored under share/tsearch\_data).

```

test=# SELECT * FROM ts_parse('zhparser', '#####');
 tokid | token
-----+-----
    118 | ##
    110 | #

```

 tokid | token
-----+-----
  118 | ##
  110 | #
  120 | #####

```

## F.77. pldebugger

LightDB pl/pgsql Debugger API. This module is a set of shared libraries which implement an API for debugging pl/pgsql functions on LightDB lightDB 13.8-23.2 and above.

### F.77.1. Installation

Edit your lightdb.conf file, and modify the shared\_preload\_libraries config option to look like:

```
shared_preload_libraries = '$libdir/plugin_debugger'
```

- plugin\_debugger must be the last extension, or debug may not be effect. - Restart LightDB for the new setting to take effect.

- Run the following command in the database or databases that you wish to debug functions in:

```
CREATE EXTENSION pldbgapi;
```

### F.77.2. Usage

Connect navicat to the database containing the functions you wish to debug. Right-click the function to debug, and select Debugging->Debug to execute and debug the function immediately, or select Debugging->Set Global Breakpoint to set a breakpoint on the function. This will cause the debugger to wait for another session (such as a backend servicing a web app) to execute the function and allow you to debug in-context. For further information, please see the navicat documentation.

### F.77.3. Architecture

The debugger consists of three parts: 1. The client. This is typically a GUI displays the source code, current stack frame, variables etc, and allows the user to set breakpoints and step through the code. The client can reside on a different host than the database server. 2. The target backend. This is the backend that runs the code being debugged. The plugin\_debugger.so library must be loaded into the

target backend. 3. Debugging proxy. This is another backend process that the client is connected to. The API functions, `pldbg_*` in `pldbgapi.so` library, are run in this backend. The client is to connected to the debugging proxy using a regular `libpq` connection. When a debugging session is active, the proxy is connected to the target via a socket. The protocol between the proxy and the target backend is not visible to others, and is subject to change. The `pldbg_*` API functions form the public interface to the debugging facility. debugger client \*----- libpq -----\* Proxy backend (navicat) \* | pldebugger socket connection | \* application client \*----- libpq -----\* Target backend

## F.78. It\_t3sdk

This LightDB extension implements JRES's T3 requests.

### F.78.1. Installation

To install the `t3sdk`, CRES's C client library is needed, and the default version is CRES2.0.V202302.00.000. This library can be downloaded from HUNDSUN

Download CRES's SDK and unzip, directory such as :

```
acm/
dev/
  client_demo/T3SDK/c++/linux.x64/lib/libt3sdk.so
  client_demo/T3SDK_C/linux.x64/lib/libt3sdk_c.so
docker/
instance/
tools/
```

The CRES's SDK `libt3sdk.so` and `libt3sdk_c.so` must add to `LD_LIBRARY_PATH`.

If you first install, use `CREATE EXTENSION t3sdk`.

If you already installed a previous version and you just want to upgrade, then `ALTER EXTENSION t3sdk UPDATE`.

### F.78.2. Concepts

Every T3 call is a made up of list of `VARCHAR` and an response of `t3sdk_response`.

Every times request to T3's service, the backend process hold on connection until that process exit. The key is server's address and port, and the value is connection handle.

		List of functions	
Schema	Name	Result data type	Argument
data types			
	Type		
public	<code>t3sdk_send</code>	<code>t3sdk_response</code>	<code>t_address</code>
	character varying, groups character varying, version character varying, function_id character varying, function_args character varying		func

Column	Type	Collation	Nullable
content	character varying		

### F.78.3. Functions

- `t3sdk_send(t_address VARCHAR, groups VARCHAR, service VARCHAR, version VARCHAR, function_id VARCHAR, function_args VARCHAR)` returns `t3sdk_response`

By default a 60 second timeout is set for the send of a request. If a different timeout is desired the following GUC variable can be used to set it in milliseconds:

```
t3sdk.t3_send_timeout_msec = 60000
```

By default a 60 second timeout is set for the rcv of a request. If a different timeout is desired the following GUC variable can be used to set it in milliseconds:

```
t3sdk.t3_rcv_timeout_msec = 60000
```

If a different T3's license is desired the following GUC variable can be used to set:

```
t3sdk.t3_license_no = 'HS-HUNDSUN001-FBASE2-0000-4ePWxzscBVtY9ZKdgDKhSyk2'
```

### F.78.4. Examples

```
-- send t3 request
select * from t3sdk_send('10.20.30.193:18082', 'g',
'repo-app', 'v', 'getExpressInfoNdb', '');
```

content

```
-----
{"result":
[{"express_id":"a","order_id":"1","express_no":"123456789","company":"#
###1","create_datetime":"20230407010201","status":"0"},
{"express_id":"b","order_id":"2","express_no":"123456789","company":"#
###2","create_dat
etime":"20230407010201","status":"0"}]}
(1 row)
```

### F.79. It\_http

This LightDB extension implements http requests.

## F.79.1. Installation

If you first install, use `CREATE EXTENSION http`.

If you already installed a previous version and you just want to upgrade, then `ALTER EXTENSION http UPDATE`.

## F.79.2. Concepts

Every HTTP call is a made up of an `http_request` and an `http_response`.

```
Composite type "public.http_request"
```

Column	Type	Modifiers
method	http_method	
uri	character varying	
headers	http_header[]	
content_type	character varying	
content	character varying	

```
Composite type "public.http_response"
```

Column	Type	Modifiers
status	integer	
content_type	character varying	
headers	http_header[]	
content	character varying	

The utility functions, `http_get()`, `http_post()`, `http_put()`, `http_delete()` and `http_head()` are just wrappers around a master function, `http(http_request)` that returns `http_response`.

The `headers` field for requests and response is a LightDB array of type `http_header` which is just a simple tuple.

```
Composite type "public.http_header"
```

Column	Type	Modifiers
field	character varying	
value	character varying	

As seen in the examples, you can unspool the array of `http_header` tuples into a result set using the LightDB `unnest()` function on the array. From there you select out the particular header you are interested in.

## F.79.3. Functions

- `http_header(field VARCHAR, value VARCHAR)` returns `http_header`
- `http(request http_request)` returns `http_response`
- `http_get(uri VARCHAR)` returns `http_response`

- `http_get(uri VARCHAR, data JSONB)` returns `http_response`
- `http_post(uri VARCHAR, content VARCHAR, content_type VARCHAR)` returns `http_response`
- `http_post(uri VARCHAR, data JSONB)` returns `http_response`
- `http_put(uri VARCHAR, content VARCHAR, content_type VARCHAR)` returns `http_response`
- `http_patch(uri VARCHAR, content VARCHAR, content_type VARCHAR)` returns `http_response`
- `http_delete(uri VARCHAR, content VARCHAR, content_type VARCHAR)` returns `http_response`
- `http_head(uri VARCHAR)` returns `http_response`
- `http_set_curlopt(curlopt VARCHAR, value varchar)` returns `boolean`
- `http_reset_curlopt()` returns `boolean`
- `http_list_curlopt()` returns `setof(curlopt text, value text)`
- `urlencode(string VARCHAR)` returns `text`
- `urlencode(data JSONB)` returns `text`

## F.79.4. CURL Options

Select CURL options<sup>15</sup> are available to set using the `http_set_curlopt(curlopt VARCHAR, value varchar)` function.

- `CURLOPT_DNS_SERVERS`<sup>16</sup>
- `CURLOPT_PROXY`<sup>17</sup>
- `CURLOPT_PRE_PROXY`<sup>18</sup>
- `CURLOPT_PROXYPORT`<sup>19</sup>
- `CURLOPT_PROXYUSERPWD`<sup>20</sup>

## F.79.5. Keep-Alive and Timeouts

The `http_reset_curlopt()` approach described above is recommended. The global variables below will be deprecated and removed over time.

By default each request uses a fresh connection and assures that the connection is closed when the request is done. This behavior reduces the chance of consuming system resources (sockets) as the extension runs over extended periods of time.

High-performance applications may wish to enable keep-alive and connection persistence to reduce latency and enhance throughput. The following GUC variable changes the behavior of the `http` extension to maintain connections as long as possible:

```
http.keepalive = 'on'
```

By default a 60 second timeout is set for the completion of a request. If a different timeout is desired the following GUC variable can be used to set it in milliseconds:

```
http.timeout_msec = 60000
```

# Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding the modules that can be found in the `contrib` directory of the LightDB distribution. See Appendix F for more information about the `contrib` section in general and server extensions and plug-ins found in `contrib` specifically.

This appendix covers utility programs found in `contrib`. Once installed, either from source or a packaging system, they are found in the `bin` directory of the LightDB installation and can be used like any other program.

## G.1. Client Applications

This section covers LightDB client applications in `contrib`. They can be run from anywhere, independent of where the database server resides. See also [LightDB Client Applications](#) for information about client applications that are part of the core LightDB distribution.

## oid2name

oid2name — resolve OIDs and file nodes in a LightDB data directory

## Synopsis

oid2name [*option...*]

## Description

oid2name is a utility program that helps administrators to examine the file structure used by LightDB. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 64.

### Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

## Options

oid2name accepts the following command-line arguments:

`-f filenode`

`--filenode=filenode`

show info for table with filenode *filenode*.

`-i`

`--indexes`

include indexes and sequences in the listing.

`-o oid`

`--oid=oid`

show info for table with OID *oid*.

`-q`

`--quiet`

omit headers (useful for scripting).

`-s`

`--tablespaces`

show tablespace OIDs.

`-S`

`--system-objects`

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas).

`-t tablename_pattern`  
`--table=tablename_pattern`

show info for table(s) matching *tablename\_pattern*.

`-V`  
`--version`

Print the oid2name version and exit.

`-x`  
`--extended`

display more information about each object shown: tablespace name, schema name, and OID.

`-?`  
`--help`

Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

`-d database`  
`--dbname=database`

database to connect to.

`-h host`  
`--host=host`

database server's host.

`-H host`

database server's host. Use of this parameter is *deprecated* as of LightDB 12.

`-p port`  
`--port=port`

database server's port.

`-U username`  
`--username=username`

user name to connect as.

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a LIKE pattern, so you can use things like `f00%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-S` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

## Environment

LTHOST  
LTPORT  
LTUSER

Default connection parameters.

This utility, like most other LightDB utilities, also uses the environment variables supported by libpq (see Section 32.14).

The environment variable `LT_COLOR` specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

## Notes

`oid2name` requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

## Examples

```
$ # what's in this database server, anyway?
$ oid2name

```

## Author

B. Palmer <bpalmer@crimelabs.net>

## vacuumlo

vacuumlo — remove orphaned large objects from a LightDB database

## Synopsis

```
vacuumlo [option...] dbname...
```

## Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a LightDB database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the `lo` module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

## Options

vacuumlo accepts the following command-line arguments:

```
-l limit  
--limit=limit
```

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding `max_locks_per_transaction`. Set the limit to zero if you want all removals done in a single transaction.

```
-n  
--dry-run
```

Don't remove anything, just show what would be done.

```
-v  
--verbose
```

Write a lot of progress messages.

```
-V  
--version
```

Print the vacuumlo version and exit.

```
-?  
--help
```

Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

```
-h host  
--host=host
```

Database server's host.

`-p port`  
`--port=port`

Database server's port.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `vacuumlo` to prompt for a password before connecting to a database.

This option is never essential, since `vacuumlo` will automatically prompt for a password if the server demands password authentication. However, `vacuumlo` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

`LTHOST`  
`LTPORT`  
`LTUSER`

Default connection parameters.

This utility, like most other LightDB utilities, also uses the environment variables supported by `libpq` (see Section 32.14).

The environment variable `LT_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

`vacuumlo` works by the following method: First, `vacuumlo` builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Peter Mount <[peter@retep.org.uk](mailto:peter@retep.org.uk)>

## G.2. Server Applications

This section covers LightDB server-related applications in `contrib`. They are typically run on the host where the database server resides. See also `LightDB Server Applications` for information about server applications that are part of the core LightDB distribution.

## lt\_standby

lt\_standby — supports the creation of a LightDB warm standby server

## Synopsis

```
lt_standby [option...] archiveLocation nextwalfile walfilepath  
[restartwalfile]
```

## Description

lt\_standby supports creation of a “warm standby” database server. It is designed to be a production-ready program, as well as a customizable template should you require specific modifications.

lt\_standby is designed to be a waiting `restore_command`, which is needed to turn a standard archive recovery into a warm standby operation. Other configuration is required as well, all of which is described in the main server manual (see Section 24.2).

To configure a standby server to use lt\_standby, put this into its `lightdb.conf` configuration file:

```
restore_command = 'lt_standby archiveDir %f %p %r'
```

where `archiveDir` is the directory from which WAL segment files should be restored.

If `restartwalfile` is specified, normally by using the `%r` macro, then all WAL files logically preceding this file will be removed from `archiveLocation`. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the `archiveLocation` is a transient staging area for this particular standby server, but *not* when the `archiveLocation` is intended as a long-term WAL archive area.

lt\_standby assumes that `archiveLocation` is a directory readable by the server-owning user. If `restartwalfile` (or `-k`) is specified, the `archiveLocation` directory must be writable too.

There are two ways to fail over to a “warm standby” database server when the master server fails:

### Smart Failover

In smart failover, the server is brought up after applying all WAL files available in the archive. This results in zero data loss, even if the standby server has fallen behind, but if there is a lot of unapplied WAL it can be a long time before the standby server becomes ready. To trigger a smart failover, create a trigger file containing the word `smart`, or just create it and leave it empty.

### Fast Failover

In fast failover, the server is brought up immediately. Any WAL files in the archive that have not yet been applied will be ignored, and all transactions in those files are lost. To trigger a fast failover, create a trigger file and write the word `fast` into it. lt\_standby can also be configured to execute a fast failover automatically if no new WAL file appears within a defined interval.

## Options

lt\_standby accepts the following command-line arguments:

`-c`

Use `cp` or `copy` command to restore WAL files from archive. This is the only supported behavior so this option is useless.

-d

Print lots of debug logging output on `stderr`.

-k

Remove files from *archive\_location* so that no more than this many WAL files before the current one are kept in the archive. Zero (the default) means not to remove any files from *archive\_location*. This parameter will be silently ignored if *restartwalfile* is specified, since that specification method is more accurate in determining the correct archive cut-off point. Use of this parameter is *deprecated* as of LightDB 8.3; it is safer and more efficient to specify a *restartwalfile* parameter. A too small setting could result in removal of files that are still needed for a restart of the standby server, while a too large setting wastes archive space.

-r *maxretries*

Set the maximum number of times to retry the copy command if it fails (default 3). After each failure, we wait for *sleeptime* \* *num\_retries* so that the wait time increases progressively. So by default, we will wait 5 secs, 10 secs, then 15 secs before reporting the failure back to the standby server. This will be interpreted as end of recovery and the standby will come up fully as a result.

-s *sleeptime*

Set the number of seconds (up to 60, default 5) to sleep between tests to see if the WAL file to be restored is available in the archive yet. The default setting is not necessarily recommended; consult Section 24.2 for discussion.

-t *triggerfile*

Specify a trigger file whose presence should cause failover. It is recommended that you use a structured file name to avoid confusion as to which server is being triggered when multiple servers exist on the same system; for example `/tmp/pgsql.trigger.5432`.

-V

--version

Print the `lt_standby` version and exit.

-w *maxwaittime*

Set the maximum number of seconds to wait for the next WAL file, after which a fast failover will be performed. A setting of zero (the default) means wait forever. The default setting is not necessarily recommended; consult Section 24.2 for discussion.

-?

--help

Show help about `lt_standby` command line arguments, and exit.

## Notes

`lt_standby` is designed to work with LightDB 8.2 and later.

LightDB 8.3 provides the `%r` macro, which is designed to let `lt_standby` know the last file it needs to keep. With LightDB 8.2, the `-k` option must be used if archive cleanup is required. This option remains available in 8.3, but its use is deprecated.

LightDB 8.4 provides the `recovery_end_command` option. Without this option a leftover trigger file can be hazardous.

`lt_standby` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

## Examples

On Linux or Unix systems, you might use:

```
archive_command = 'cp %p ../archive/%f'

restore_command = 'lt_standby -d -s 2 -t /tmp/
pgsql.trigger.5442 ../archive %f %p %r 2>>standby.log'

recovery_end_command = 'rm -f /tmp/pgsql.trigger.5442'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby (enabling use of `ln`). This will:

- produce debugging output in `standby.log`
- sleep for 2 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `/tmp/pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

On Windows, you might use:

```
archive_command = 'copy %p ...\\archive\\%f'

restore_command = 'lt_standby -d -s 5 -t C:\pgsql.trigger.5442 ...
\archive %f %p %r 2>>standby.log'

recovery_end_command = 'del C:\pgsql.trigger.5442'
```

Note that backslashes need to be doubled in the `archive_command`, but *not* in the `restore_command` or `recovery_end_command`. This will:

- use the `copy` command to restore WAL files from archive
- produce debugging output in `standby.log`
- sleep for 5 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `C:\pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

The `copy` command on Windows sets the final file size before the file is completely copied, which would ordinarily confuse `lt_standby`. Therefore `lt_standby` waits `sleep_time` seconds once it sees the proper file size. GNUWin32's `cp` sets the file size only after the file copy is complete.

Since the Windows example uses `copy` at both ends, either or both servers might be accessing the archive directory across the network.

# Appendix H. External Projects

LightDB is a complex software project, and managing the project is difficult. We have found that many enhancements to LightDB can be more efficiently developed separately from the core project.

## H.1. Client Interfaces

There are only two client interfaces included in the base LightDB distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- ECPG is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in LightDB itself.

All other language interfaces are external projects and are distributed separately. Table H.1 includes a list of some of these projects. Note that some of these packages might not be released under the same license as LightDB. For more information on each language interface, including licensing terms, refer to its website and documentation.

**Table H.1. Externally Maintained Client Interfaces**

Name	Language	Comments	Website
DBD::Pg	Perl	Perl DBI driver	<a href="https://metacpan.org/release/DBD-Pg">https://metacpan.org/release/DBD-Pg</a>
JDBC	Java	Type 4 JDBC driver	<a href="https://www.light-pg.com/docs/LTJDBC/current/index.html">https://www.light-pg.com/docs/LTJDBC/current/index.html</a>
libpqxx	C++	C++ interface	<a href="https://pqxx.org/">https://pqxx.org/</a>
node-postgres	JavaScript	Node.js driver	<a href="https://node-postgres.com/">https://node-postgres.com/</a>

psycopg	Python	DB API 2.0-compliant	<a href="https://www.psycopg.org/">https://www.psycopg.org/</a>

## H.2. Administration Tools

There are several administration tools available for LightDB. The most popular is pgAdmin<sup>1</sup>, and there are several commercially available ones as well.

## H.3. Procedural Languages

---

<sup>1</sup> <https://www.pgadmin.org/>

LightDB includes several procedural languages with the base distribution: PL/pgSQL, PL/oraSQL.

In addition, there are a number of procedural languages that are developed and maintained outside the core LightDB distribution. Table H.2 lists some of these packages. Note that some of these projects might not be released under the same license as LightDB. For more information on each procedural language, including licensing information, refer to its website and documentation.

**Table H.2. Externally Maintained Procedural Languages**

Name	Language	Website
PL/Java	Java	<a href="https://tada.github.io/pljava/">https://tada.github.io/pljava/</a>
PL/Lua	Lua	<a href="https://github.com/pllua/pllua-ng">https://github.com/pllua/pllua-ng</a>
PL/R	R	<a href="https://github.com/postgres-plr/plr">https://github.com/postgres-plr/plr</a>
PL/sh	Unix shell	<a href="https://github.com/petere/plsh">https://github.com/petere/plsh</a>
PL/v8	JavaScript	<a href="https://github.com/plv8/plv8">https://github.com/plv8/plv8</a>

## H.4. Extensions

LightDB is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The `contrib/` directory shipped with the source code contains several extensions, which are described in Appendix F. Other extensions are developed independently, like PostGIS<sup>2</sup>. Even LightDB replication solutions can be developed externally. For example, Slony-I<sup>3</sup> is a popular master/standby replication solution that is developed independently from the core project.

<sup>2</sup> <https://postgis.net/>

<sup>3</sup> <https://www.slony.info>

---

# Appendix I. LightDB Limits

Table I.1 describes various hard limits of LightDB. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

**Table I.1. LightDB Limitations**

Item	Upper Limit	Comment
database size	unlimited	
number of databases	4,294,950,911	
relations per database	1,431,650,303	
relation size	32 TB	with the default BLCKSZ of 8192 bytes
rows per table	limited by the number of tuples that can fit onto 4,294,967,295 pages	
columns per table	1600	further limited by tuple size fitting on a single page; see note below
columns in a result set	1664	
field size	1 GB	
identifier length	63 bytes	can be increased by recompiling LightDB
indexes per table	unlimited	constrained by maximum relations per database
columns per index	32	can be increased by recompiling LightDB
partition keys	32	can be increased by recompiling LightDB

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

---

# Appendix J. Acronyms

This is a list of acronyms commonly used in the LightDB documentation and in discussions about LightDB.

# Appendix K. Glossary

This is a list of terms and their meaning in the context of LightDB and relational database systems in general.

ACID	<i>Atomicity, Consistency, Isolation, and Durability.</i> This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.
Aggregate function (routine)	<p>A <i>function</i> that combines (<i>aggregates</i>) multiple input values, for example by counting, averaging or adding, yielding a single output value.</p> <p>For more information, see Section 9.21.</p> <p>See Also Window function (routine).</p>
Analytic function	See Window function (routine).
Analyze (operation)	<p>The process of collecting statistics from data in <i>tables</i> and other <i>relations</i> to help the <i>query planner</i> to make decisions about how to execute <i>queries</i>.</p> <p>(Don't confuse this term with the <code>ANALYZE</code> option to the <code>EXPLAIN</code> command.)</p> <p>For more information, see <code>ANALYZE</code>.</p>
Atomic	<p>In reference to a <i>datum</i>: the fact that its value cannot be broken down into smaller components.</p> <p>In reference to a <i>database transaction</i>: see <i>atomicity</i>.</p>
Atomicity	The property of a <i>transaction</i> that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.
Attribute	An element with a certain name and data type found within a <i>tuple</i> .
Autovacuum (process)	<p>A set of background processes that routinely perform <i>vacuum</i> and <i>analyze</i> operations.</p> <p>For more information, see Section 22.1.6.</p>
Backend (process)	<p>Process of an <i>instance</i> which acts on behalf of a <i>client session</i> and handles its requests.</p> <p>(Don't confuse this term with the similar terms <i>Background Worker</i> or <i>Background Writer</i>).</p>
Background worker (process)	<p>Process within an <i>instance</i>, which runs system- or user-supplied code. Serves as infrastructure for several features in LightDB, such as <i>logical replication</i> and <i>parallel queries</i>. In addition, <i>Extensions</i> can add custom background worker processes.</p> <p>For more information, see Chapter 44.</p>
Background writer (process)	A process that writes dirty <i>data pages</i> from <i>shared memory</i> to the file system. It wakes up periodically, but works only for a

	<p>short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes.</p> <p>For more information, see Section 17.4.5.</p>
Bloat	<p>Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.</p>
Cast	<p>A conversion of a <i>datum</i> from its current data type to another data type.</p> <p>For more information, see CREATE CAST.</p>
Catalog	<p>The SQL standard uses this term to indicate what is called a <i>database</i> in LightDB's terminology.</p> <p>(Don't confuse this term with <i>system catalog</i>).</p> <p>For more information, see Section 20.1.</p>
Check constraint	<p>A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or more <i>attributes</i>. The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations.</p> <p>For more information, see Section 5.4.</p>
Checkpoint	<p>A point in the <i>WAL</i> sequence at which it is guaranteed that the heap and index data files have been updated with all information from <i>shared memory</i> modified before that checkpoint; a <i>checkpoint record</i> is written and flushed to <i>WAL</i> to mark that point.</p> <p>A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when predefined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command CHECKPOINT.</p> <p>For more information, see Section 27.4.</p>
Checkpointer (process)	<p>A specialized process responsible for executing checkpoints.</p>
Class (archaic)	<p>See Relation.</p>
Client (process)	<p>Any process, possibly remote, that establishes a <i>session</i> by <i>connecting</i> to an <i>instance</i> to interact with a <i>database</i>.</p>
Column	<p>An <i>attribute</i> found in a <i>table</i> or <i>view</i>.</p>
Commit	<p>The act of finalizing a <i>transaction</i> within the <i>database</i>, which makes it visible to other transactions and assures its <i>durability</i>.</p> <p>For more information, see COMMIT.</p>
Concurrency	<p>The concept that multiple independent operations happen within the <i>database</i> at the same time. In LightDB, concurrency is controlled by the <i>multiversion concurrency control</i> mechanism.</p>

Connection	<p>An established line of communication between a client process and a <i>backend</i> process, usually over a network, supporting a <i>session</i>. This term is sometimes used as a synonym for session.</p> <p>For more information, see Section 17.3.</p>
Consistency	<p>The property that the data in the <i>database</i> is always in compliance with <i>integrity constraints</i>. Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved by the time it commits, such a transaction is automatically <i>rolled back</i>. This is one of the ACID properties.</p>
Constraint	<p>A restriction on the values of data allowed within a <i>table</i>, or in attributes of a <i>domain</i>.</p> <p>For more information, see Section 5.4.</p>
Data area	<p>See Data directory.</p>
Database	<p>A named collection of <i>local SQL objects</i>.</p> <p>For more information, see Section 20.1.</p>
Database cluster	<p>A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a <i>cluster</i>.</p> <p>In LightDB, the term <i>cluster</i> is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command CLUSTER.)</p>
Database server	<p>See Instance.</p>
Data directory	<p>The base directory on the file system of a <i>server</i> that contains all data files and subdirectories associated with a <i>database cluster</i> (with the exception of <i>tablespaces</i>, and optionally <i>WAL</i>). The environment variable <code>LTDATA</code> is commonly used to refer to the data directory.</p> <p>A <i>cluster's</i> storage space comprises the data directory plus any additional tablespaces.</p> <p>For more information, see Section 64.1.</p>
Data page	<p>The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to <i>shared buffers</i> where they can be modified, becoming <i>dirty</i>. They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.</p>
Datum	<p>The internal representation of one value of an SQL data type.</p>
Delete	<p>An SQL command which removes <i>rows</i> from a given <i>table</i> or <i>relation</i>.</p> <p>For more information, see DELETE.</p>
Durability	<p>The assurance that once a <i>transaction</i> has been <i>committed</i>, the changes remain even after a system failure or crash. This is one of the ACID properties.</p>

Epoch	See Transaction ID.
Extension	<p>A software add-on package that can be installed on an <i>instance</i> to get extra features.</p> <p>For more information, see Section 36.17.</p>
File segment	<p>A physical file which stores data for a given <i>relation</i>. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.</p> <p>For more information, see Section 64.1.</p> <p>(Don't confuse this term with the similar term <i>WAL segment</i>).</p>
Foreign data wrapper	<p>A means of representing data that is not contained in the local <i>database</i> so that it appears as if were in local <i>table(s)</i>. With a foreign data wrapper it is possible to define a <i>foreign server</i> and <i>foreign tables</i>.</p> <p>For more information, see CREATE FOREIGN DATA WRAPPER.</p>
Foreign key	A type of <i>constraint</i> defined on one or more <i>columns</i> in a <i>table</i> which requires the value(s) in those <i>columns</i> to identify zero or one <i>row</i> in another (or, infrequently, the same) <i>table</i> .
Foreign server	<p>A named collection of <i>foreign tables</i> which all use the same <i>foreign data wrapper</i> and have other configuration values in common.</p> <p>For more information, see CREATE SERVER.</p>
Foreign table (relation)	<p>A <i>relation</i> which appears to have <i>rows</i> and <i>columns</i> similar to a regular <i>table</i>, but will forward requests for data through its <i>foreign data wrapper</i>, which will return <i>result sets</i> structured according to the definition of the <i>foreign table</i>.</p> <p>For more information, see CREATE FOREIGN TABLE.</p>
Fork	Each of the separate segmented file sets in which a relation is stored. The <i>main fork</i> is where the actual data resides. There also exist two secondary forks for metadata: the <i>free space map</i> and the <i>visibility map</i> . <i>Unlogged relations</i> also have an <i>init fork</i> .
Free space map (fork)	<p>A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size.</p> <p>For more information, see Section 64.3.</p>
Function (routine)	<p>A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via SELECT. Certain functions can return <i>sets</i>; those are called <i>set-returning functions</i>.</p> <p>Functions can also be used for <i>triggers</i> to invoke.</p>

	For more information, see CREATE FUNCTION.
Grant	An SQL command that is used to allow a <i>user</i> or <i>role</i> to access specific objects within the <i>database</i> .  For more information, see GRANT.
Heap	Contains the values of <i>row</i> attributes (i.e., the data) for a <i>relation</i> . The heap is realized within one or more <i>file segments</i> in the relation's <i>main fork</i> .
Host	A computer that communicates with other computers over a network. This is sometimes used as a synonym for <i>server</i> . It is also used to refer to a computer where <i>client processes</i> run.
Index (relation)	A <i>relation</i> that contains data derived from a <i>table</i> or <i>materialized view</i> . Its internal structure supports fast retrieval of and access to the original data.  For more information, see CREATE INDEX.
Insert	An SQL command used to add new data into a <i>table</i> .  For more information, see INSERT.
Instance	A group of backend and auxiliary processes that communicate using a common shared memory area. One <i>postmaster process</i> manages the instance; one instance manages exactly one <i>database cluster</i> with all its databases. Many instances can run on the same <i>server</i> as long as their TCP ports do not conflict.  The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, <i>connections</i> to <i>client processes</i> , privilege verification, crash recovery, replication, etc.
Isolation	The property that the effects of a transaction are not visible to <i>concurrent transactions</i> before it commits. This is one of the ACID properties.  For more information, see Section 13.2.
Join	An operation and SQL keyword used in <i>queries</i> for combining data from multiple <i>relations</i> .
Key	A means of identifying a <i>row</i> within a <i>table</i> or other <i>relation</i> by values contained within one or more <i>attributes</i> in that relation.
Lock	A mechanism that allows a process to limit or prevent simultaneous access to a resource.
Log file	Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc.  For more information, see Section 22.3.
Logged	A <i>table</i> is considered <i>logged</i> if changes to it are sent to the <i>WAL</i> . By default, all regular tables are logged. A table can be specified as <i>unlogged</i> either at creation time or via the ALTER TABLE command.

Logger (process)	<p>If activated, the process writes information about database events into the current <i>log file</i>. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called <i>syslogger</i>.</p> <p>For more information, see Section 17.8.</p>
Log record	Archaic term for a <i>WAL record</i> .
Master (server)	See Primary (server).
Materialized	<p>The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly.</p> <p>This term is used in <i>materialized view</i>, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.</p> <p>This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.</p>
Materialized view (relation)	<p>A <i>relation</i> that is defined by a <code>SELECT</code> statement (just like a <i>view</i>), but stores data in the same way that a <i>table</i> does. It cannot be modified via <code>INSERT</code>, <code>UPDATE</code>, or <code>DELETE</code> operations.</p> <p>For more information, see <code>CREATE MATERIALIZED VIEW</code>.</p>
Multi-version concurrency control (MVCC)	A mechanism designed to allow several <i>transactions</i> to be reading and writing the same rows without one process causing other processes to stall. In LightDB, MVCC is implemented by creating copies ( <i>versions</i> ) of <i>tuples</i> as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.
Null	A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.
Optimizer	See Query planner.
Parallel query	The ability to handle parts of executing a <i>query</i> to take advantage of parallel processes on servers with multiple CPUs.
Partition	<p>One of several disjoint (not overlapping) subsets of a larger set.</p> <p>In reference to a <i>partitioned table</i>: One of the tables that each contain part of the data of the partitioned table, which is said to be the <i>parent</i>. The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created.</p> <p>In reference to a <i>window function</i> in a <i>query</i>, a partition is a user-defined criterion that identifies which neighboring <i>rows</i> of the <i>query's result set</i> can be considered by the function.</p>
Partitioned table (relation)	A <i>relation</i> that is in semantic terms the same as a <i>table</i> , but whose storage is distributed across several <i>partitions</i> .
Postmaster (process)	The very first process of an <i>instance</i> . It starts and manages the other auxiliary processes and creates <i>backend processes</i> on demand.

	For more information, see Section 16.3.
Primary key	A special case of a <i>unique constraint</i> defined on a <i>table</i> or other <i>relation</i> that also guarantees that all of the <i>attributes</i> within the <i>primary key</i> do not have <i>null</i> values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.
Primary (server)	When two or more <i>databases</i> are linked via <i>replication</i> , the <i>server</i> that is considered the authoritative source of information is called the <i>primary</i> , also known as a <i>master</i> .
Procedure (routine)	A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as COMMIT and ROLLBACK. They are invoked via the CALL command.  For more information, see CREATE PROCEDURE.
Query	A request sent by a client to a <i>backend</i> , usually to return results or to modify data on the database.
Query planner	The part of LightDB that is devoted to determining ( <i>planning</i> ) the most efficient way to execute <i>queries</i> . Also known as <i>query optimizer</i> , <i>optimizer</i> , or simply <i>planner</i> .
Record	See Tuple.
Recycling	See WAL file.
Referential integrity	A means of restricting data in one <i>relation</i> by a <i>foreign key</i> so that it must have matching data in another <i>relation</i> .
Relation	The generic term for all objects in a <i>database</i> that have a name and a list of <i>attributes</i> defined in a specific order. <i>Tables</i> , <i>sequences</i> , <i>views</i> , <i>foreign tables</i> , <i>materialized views</i> , composite types, and <i>indexes</i> are all relations.  More generically, a relation is a set of tuples; for example, the result of a query is also a relation.  In LightDB, <i>Class</i> is an archaic synonym for <i>relation</i> .
Replica (server)	A <i>database</i> that is paired with a <i>primary</i> database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the <i>primary</i> becomes unavailable.
Replication	The act of reproducing data on one <i>server</i> onto another server called a <i>replica</i> . This can take the form of <i>physical replication</i> , where all file changes from one server are copied verbatim, or <i>logical replication</i> where a defined subset of data changes are conveyed using a higher-level representation.
Result set	A <i>relation</i> transmitted from a <i>backend process</i> to a <i>client</i> upon the completion of an SQL command, usually a SELECT but it can be an INSERT, UPDATE, or DELETE command if the RETURNING clause is specified.

	<p>The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a <i>subquery</i>.</p>
Revoke	<p>A command to prevent access to a named set of <i>database</i> objects for a named list of <i>roles</i>.</p> <p>For more information, see REVOKE.</p>
Role	<p>A collection of access privileges to the <i>instance</i>. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple <i>users</i> need the same privileges.</p> <p>For more information, see CREATE ROLE.</p>
Rollback	<p>A command to undo all of the operations performed since the beginning of a <i>transaction</i>.</p> <p>For more information, see ROLLBACK.</p>
Routine	<p>A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be <i>functions</i> (including set-returning functions and <i>trigger functions</i>), <i>aggregate functions</i>, and <i>procedures</i>.</p> <p>Many routines are already defined within LightDB itself, but user-defined ones can also be added.</p>
Row	<p>See Tuple.</p>
Savepoint	<p>A special mark in the sequence of steps in a <i>transaction</i>. Data modifications after this point in time may be reverted to the time of the savepoint.</p> <p>For more information, see SAVEPOINT.</p>
Schema	<p>A schema is a namespace for <i>SQL objects</i>, which all reside in the same <i>database</i>. Each SQL object must reside in exactly one schema.</p> <p>All system-defined SQL objects reside in schema <code>pg_catalog</code>.</p> <p>More generically, the term <i>schema</i> is used to mean all data descriptions (<i>table</i> definitions, <i>constraints</i>, comments, etc) for a given <i>database</i> or subset thereof.</p> <p>For more information, see Section 5.9.</p>
Segment	<p>See File segment.</p>
Select	<p>The SQL command used to request data from a <i>database</i>. Normally, SELECT commands are not expected to modify the <i>database</i> in any way, but it is possible that <i>functions</i> invoked within the query could have side effects that do modify data.</p> <p>For more information, see SELECT.</p>
Sequence (relation)	<p>A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate <i>primary key</i> values.</p>

Server	<p>A computer on which LightDB <i>instances</i> run. The term <i>server</i> denotes real hardware, a container, or a <i>virtual machine</i>.</p> <p>This term is sometimes used to refer to an instance or to a host.</p>
Session	<p>A state that allows a client and a backend to interact, communicating over a <i>connection</i>.</p>
Shared memory	<p>RAM which is used by the processes common to an <i>instance</i>. It mirrors parts of <i>database</i> files, provides a transient area for <i>WAL records</i>, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.</p> <p>The largest part of shared memory is known as <i>shared buffers</i> and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.</p> <p>For more information, see Section 17.4.1.</p>
SQL object	<p>Any object that can be created with a CREATE command. Most objects are specific to one database, and are commonly known as <i>local objects</i>.</p> <p>Most local objects belong to a specific <i>schema</i> in their containing database, such as <i>relations</i> (all types), <i>routines</i> (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.</p> <p>There also exist local objects that do not belong to schemas; some examples are <i>extensions</i>, <i>data type casts</i>, and <i>foreign data wrappers</i>. The names of such objects of the same type are enforced to be unique within the database.</p> <p>Other object types, such as <i>roles</i>, <i>tablespaces</i>, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are called <i>global objects</i>. The names of such objects are enforced to be unique within the whole database cluster.</p> <p>For more information, see Section 20.1.</p>
SQL standard	<p>A series of documents that define the SQL language.</p>
Standby (server)	<p>See Replica (server).</p>
Stats collector (process)	<p>This process collects statistical information about the <i>instance's</i> activities.</p> <p>For more information, see Section 25.2.</p>
System catalog	<p>A collection of <i>tables</i> which describe the structure of all <i>SQL objects</i> of the instance. The system catalog resides in the schema <code>pg_catalog</code>. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier <i>views</i>, also in schema <code>pg_catalog</code>, offer more convenient access to some of that information, while additional tables and views exist in schema <code>information_schema</code> (see Chapter 35) that expose some of</p>

	<p>the same and additional information as mandated by the <i>SQL standard</i>.</p> <p>For more information, see Section 5.9.</p>
Table	<p>A collection of <i>tuples</i> having a common data structure (the same number of <i>attributes</i>, in the same order, having the same name and type per position). A table is the most common form of <i>relation</i> in LightDB.</p> <p>For more information, see CREATE TABLE.</p>
Tablespace	<p>A named location on the server file system. All <i>SQL objects</i> which require storage beyond their definition in the <i>system catalog</i> must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called <code>pg_default</code>.</p> <p>For more information, see Section 20.6.</p>
Temporary table	<p><i>Tables</i> that exist either for the lifetime of a <i>session</i> or a <i>transaction</i>, as specified at the time of creation. The data in them is not visible to other sessions, and is not <i>logged</i>. Temporary tables are often used to store intermediate data for a multi-step operation.</p> <p>For more information, see CREATE TABLE.</p>
TOAST	<p>A mechanism by which large attributes of table rows are split and stored in a secondary table, called the <i>TOAST table</i>. Each relation with large attributes has its own TOAST table.</p> <p>For more information, see Section 64.2.</p>
Transaction	<p>A combination of commands that must act as a single <i>atomic</i> command: they all succeed or all fail as a single unit, and their effects are not visible to other <i>sessions</i> until the transaction is complete, and possibly even later, depending on the isolation level.</p> <p>For more information, see Section 13.2.</p>
Transaction ID	<p>The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as <i>xid</i>. When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to permit the system to run for longer than that, <i>epochs</i> are used, also 32 bits wide. When the counter reaches the maximum xid value, it starts over at 3 (values under that are reserved) and the epoch value is incremented by one. In some contexts, the epoch and xid values are considered together as a single 64-bit value.</p> <p>For more information, see Section 8.19.</p>
Transactions per second (TPS)	<p>Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.</p>
Trigger	<p>A <i>function</i> which can be defined to execute whenever a certain operation (<code>INSERT</code>, <code>UPDATE</code>, <code>DELETE</code>, <code>TRUNCATE</code>) is applied</p>

to a *relation*. A trigger executes within the same *transaction* as the statement which invoked it, and if the function fails, then the invoking statement also fails.

For more information, see CREATE TRIGGER.

Tuple	<p>A collection of <i>attributes</i> in a fixed order. That order may be defined by the <i>table</i> (or other <i>relation</i>) where the tuple is contained, in which case the tuple is often called a <i>row</i>. It may also be defined by the structure of a result set, in which case it is sometimes called a <i>record</i>.</p>
Unique constraint	<p>A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those.</p> <p>Because <i>null values</i> are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.</p>
Unlogged	<p>The property of certain <i>relations</i> that the changes to them are not reflected in the <i>WAL</i>. This disables replication and crash recovery for these relations.</p> <p>The primary use of unlogged tables is for storing transient work data that must be shared across processes.</p> <p><i>Temporary tables</i> are always unlogged.</p>
Update	<p>An SQL command used to modify <i>rows</i> that may already exist in a specified <i>table</i>. It cannot create or remove rows.</p> <p>For more information, see UPDATE.</p>
User	<p>A <i>role</i> that has the LOGIN privilege.</p>
User mapping	<p>The translation of login credentials in the local <i>database</i> to credentials in a remote data system defined by a <i>foreign data wrapper</i>.</p> <p>For more information, see CREATE USER MAPPING.</p>
Vacuum	<p>The process of removing outdated <i>tuple versions</i> from tables or materialized views, and other closely related processing required by LightDB's implementation of <i>MVCC</i>. This can be initiated through the use of the VACUUM command, but can also be handled automatically via <i>autovacuum</i> processes.</p> <p>For more information, see Section 22.1 .</p>
View	<p>A <i>relation</i> that is defined by a SELECT statement, but has no storage of its own. Any time a query references a view, the definition of the view is substituted into the query as if the user had typed it as a subquery instead of the name of the view.</p> <p>For more information, see CREATE VIEW.</p>
Visibility map (fork)	<p>A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores</p>

	two bits: the first one ( <code>all-visible</code> ) indicates that all tuples in the page are visible to all transactions. The second one ( <code>all-frozen</code> ) indicates that all tuples in the page are marked frozen.
WAL	See Write-ahead log.
WAL archiver (process)	<p>A process that saves copies of <i>WAL files</i> for the purpose of creating backups or keeping <i>replicas</i> current.</p> <p>For more information, see Section 23.3.</p>
WAL file	<p>Also known as <i>WAL segment</i> or <i>WAL segment file</i>. Each of the sequentially-numbered files that provide storage space for <i>WAL</i>. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.</p> <p>Each WAL file can be released after a <i>checkpoint</i> writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called <i>recycling</i>.</p> <p>For more information, see Section 27.5.</p>
WAL record	<p>A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (<i>replayed</i>) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.</p> <p>For more information, see Section 27.5.</p>
WAL segment	See WAL file.
WAL writer (process)	<p>A process that writes <i>WAL records</i> from <i>shared memory</i> to <i>WAL files</i>.</p> <p>For more information, see Section 17.5.</p>
Window function (routine)	<p>A type of <i>function</i> used in a <i>query</i> that applies to a <i>partition</i> of the query's <i>result set</i>; the function's result is based on values found in <i>rows</i> of the same partition or frame.</p> <p>All <i>aggregate functions</i> can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as <i>analytic functions</i>.</p> <p>For more information, see Section 3.5.</p>
Write-ahead log	The journal that keeps track of the changes in the <i>database cluster</i> as user- and system-invoked operations take place. It comprises many individual <i>WAL records</i> written sequentially to <i>WAL files</i> .

---

# Appendix L. Color Support

Most programs in the LightDB package can produce colorized console output. This appendix describes how that is configured.

## L.1. When Color is Used

To use colorized output, set the environment variable `LT_COLOR` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

## L.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `LT_COLORS` (note plural). The value is a colon-separated list of `key=value` pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

`error`

used to highlight the text “error” in error messages

`warning`

used to highlight the text “warning” in warning messages

`locus`

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:locus=01` (01;31 = bold red, 01;35 = bold magenta, 01 = bold default color).

### Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

---

# Appendix M. LightDB JDBC

The LightDB JDBC Driver allows Java programs to connect to a LightDB using standard, database independent Java code.

In addition to the standard connection parameters the driver supports a number of additional properties which can be used to specify additional driver behaviour specific to LightDB.

- *lightdbSyntaxCompatibleType* (*String*) specifies LightDB compatible type, valid values are oracle/mysql/off,default value is off. It can compatible with Oracle Database,MySQL DataBase. For example:

```
jdbc:postgresql://localhost:5432/postgres?  
lightdbSyntaxCompatibleType=oracle
```

*jdbc can compatible with Oracle*

*Database*

- *currentSchema* (*String*) specifies the schema (or several schema separated by commas) to be set in the search-path. This schema will be used to resolve unqualified object names used in statements over this connection. For example:

```
jdbc:postgresql://localhost:5432/postgres?  
currentSchema=\"$user\", oracle
```

*jdbc will automatically supplement  
public to search\_path. Actual search\_path is \"\$user\", oracle,  
public, lt\_catalog*

- *options* (*String*) specifies the guc parameter in options. The format is as follows: options=-c guc parameter name=parameter value, where the value after options needs encode. For example:

```
jdbc:postgresql://localhost:5432/postgres?  
options=-c%20search_path=\"$user\",public,oracle,lt_catalog%20-c  
%20statement_timeout=90000
```

*search\_path is part of the guc  
parameter, so you can also set search\_path*

# Appendix N. Hooks List For Extension

There are many hooks that can be used by extension to extend internal functionality. Hooks can modify behavior at different places, including when running SQL statements.

A list of available hooks is listed below

**Table N.1. Hooks list**

Position	Hook	Description
analyze.h	post_parse_analyze_hook	Hook for plugins to get control at end of parse analysis
	lt_post_parse_analyze_stmt_hook	Hook for plugins to get control at end of stmt parse analysis.
planner.h	planner_hook	Hook for plugins to get control in planner()
	create_upper_paths_hook	Hook for plugins to get control when grouping_planner() plans upper rels
	pre_create_ordinary_grouping_paths_hook	Hook for plugins to get control before create_ordinary_grouping_paths.
	lt_distribute_qual_to_rels_hook	Hook for plugins to get control of distribute qual to rels.
paths.h	set_rel_pathlist_hook	Hook for plugins to get control in set_rel_pathlist()
	set_join_pathlist_hook	Hook for plugins to get control in add_paths_to_joinrel()
	join_search_hook	Hook for plugins to replace standard_join_search()
	pushdownquals_to_subquery_hook	Hook for plugins to decide whether to pushdown quals to subquery.
planmain.h	support_semijoin_to_inner_join_hook	Hook for plugins to get control of converting semijoin to inner join.
	lt_order_qual_clauses_hook	Hook for plugins to get control of order qual clauses.
Executor.h	ExecutorStart_hook	Hook for plugins to get control in ExecutorStart()
	ExecutorRun_hook	Hook for plugins to get control in ExecutorRun()
	ExecutorFinish_hook	Hook for plugins to get control in ExecutorFinish()
	ExecutorEnd_hook	Hook for plugins to get control in ExecutorEnd()
	ExecutorCheckPerms_hook	Hook for plugins to get control in ExecCheckRTPerms()

Hooks List For Extension

Position	Hook	Description
Utility.h	ProcessUtility_hook	Hook for plugins to get control in ProcessUtility()
plancat.h	get_relation_info_hook	Hook for plugins to get control in get_relation_info()
auth.h	ClientAuthentication_hook	Hook for plugins to get control in ClientAuthentication()
explain.h	ExplainOneQuery_hook	Hook for plugins to get control in ExplainOneQuery()
	explain_get_index_name_hook	Hook for plugins to get control in explain_get_index_name()
user.h	check_password_hook	Hook to check passwords in CreateRole() and AlterRole()
elog.h	emit_log_hook	Hook for intercepting messages before they are sent to the server log
fmgr.h	needs_fmgr_hook	Hooks for function calls
	fmgr_hook	Hooks for function calls
lsyscache.h	get_attavgwidth_hook	Hook for plugins to get control in get_attavgwidth()
selfuncs.h	get_relation_stats_hook	Hooks for plugins to get control when we ask for stats
	get_index_stats_hook	Hooks for plugins to get control when we ask for stats
objectaccess.h	object_access_hook	Plugin provides a hook function matching this signature
libpq-be.h	openssl_tls_init_hook	init hook for SSL, the default sets the password callback if appropriate
rowsecurity.h	row_security_policy_hook_permissions	hooks to allow extensions to add their own security policies, it is used to add policies which are combined with the other permissive policies, using OR.
ipc.h	shmem_startup_hook	hooks to allow extensions to set up their shmem allocations.
prep.h	It_judge_can_pull_up_hook	Hook for plugins to decide is or not to pull up sub query.
	It_judge_sublink_can_pull_up_hook	Hook for plugins to decide is or not to pull up sublink.

---

# Bibliography

Selected references and readings for SQL and LightDB.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department web site<sup>1</sup>.

## SQL Reference Books

- [bowman01] *The Practical SQL Handbook*. Using SQL Variants. Fourth Edition. Judith Bowman, Sandra Emerson, and Marcy Darnovsky. ISBN 0-201-70309-2. Addison-Wesley Professional. 2001.
- [date97] *A Guide to the SQL Standard*. A user's guide to the standard database language SQL. Fourth Edition. C. J. Date and Hugh Darwen. ISBN 0-201-96426-0. Addison-Wesley. 1997.
- [date04] *An Introduction to Database Systems*. Eighth Edition. C. J. Date. ISBN 0-321-19784-4. Addison-Wesley. 2003.
